Zahvalnica

Želim da zahvalim svima koji su pomogli pri izradi ove teze. Pre svega mentoru dr Srđanu Samuroviću želim da se zahvalim na velikoj pomoći i ličnom angažovanju oko pojedinih aspekata ove teze. Zahvaljujem i dr Dragani Ilić i dr Slobodanu Ninkoviću. Zatim, zahvalna sam mnogim kolegama koji su mi u nekom trenutku pomogli korisnim sugestijama, ali i vrlo konkretno, pre svega dr Milanu Bogosavljeviću, dr Nataši Bon, Mileni Jovanović i drugima. Mnoge inostrane kolege takođe su mi pomogle savetima i to su: dr Luis Ho, Dr. Andrew West, dr Guy Worthey, dr Benjamin Alan Weaver, dr Juan Carlos Munoz-Mateos, dr Manolo Papastergis, dr Marc Sarzi, dr Michelle Cappellari, dr Kyuseok Oh, dr Jarle Brinchmann, dr Jesus Falcon Barroso i posebno HVALA dr Chien Pengu.

Naravno, izrada ove teze ne bi bila moguća bez pomoći supruga...

For my foreign colleagues, a special thanks in English – to all of you who helped when I was stuck: Dr. Luis Ho, Dr. Andrew West, Dr. Guy Worthey, Dr. Benjamin Alan Weaver, Dr. Juan Carlos Munoz-Mateos, Dr. Manolo Papastergis, Dr. Marc Sarzi, Dr. Michelle Cappellari, Dr. Kyuseok Oh, Dr. Jarle Brinchmann, Dr. Jesus Falcon Barroso and a very special thanks go to Dr. Chien Peng.

Spektroskopska i fotometrijska analiza bliskih galaksija različitih morfoloških tipova

Sažetak

Cilj ove disertacije jeste svodenje višedimenzionalnog prostora osobina galaksija na najmanji broj dimenzija, dovoljan da ih opiše. U tu svrhu primenjena je statistička analiza nad skupom parametara koji oslikavaju fundamentalne osobine galaksija, na morfološki reprezentativnom uzorku od 2180 galaksija. Uzorak galaksija korišćen u ovoj disertaciji zasnovan je na *Arecibo Legacy Fast ALFA* (skraćeno, Alfa) HI pregledu neba.

Značaj HI pregleda leži u činjenici da su galaksije birane isključivo na osnovu sadržaja gasa (HI), tako da nema optičkih selekcionih efekata. Iz ovog uzorka koji broji ~ 10000 galaksija, izdvojeno je 2180 galaksija, koje raspolazu optičkom spektroskopijom iz baze podataka *Sloan Digital Sky Survey* (skraceno, SDSS) i fotometrijom od ultraljubičastog (*Galaxy Evolution Explorer*, skraćeno GALEX), preko optičkog (SDSS) do bliskog infracrvenog dela spektra (*Two Micron All Sky Survey*, skraćeno 2MASS).

Skup analiziranih parametara odabran je uzimajući u obzir poznate korelacije između fundamentalnih osobina galaksija, oslanjajući se na prethodne radove iz ove oblasti. Parametri su detaljno testirani i međusobno upoređeni, kako bi formirali konačan skup parametra iz većeg parametarskog prostora osobina galaksija.

U svrhu izbora, tačnije određivanja i testiranja parametara, prvo je izračunata kinematika zvezda pomoću javno dostupnog programa (pPXF), sa kojim su testirane empirijske i sintetičke biblioteke zvezdanih spektara. Konkretno, izračunata je disperzija brzina zvezda i viši momenti raspodele brzina duž pravca posmatranja. Ovo je do sada najveći uzorak galaksija za koji je izmerena detaljna kinematika zvezda uključujući više momente raspodele brzina. Veličina uzorka omogućava primenu statističkih testova na

viši moment raspodele brzina (h_4) za različite grupe morfoloških tipova galaksija, koji su potvrdili ranije indikacije da eliptične i sočivaste galaksije dele poreklo.

Dalje su izvršena nova merenja jačine određenih apsorpcionih linija (Likovi indeksi), od kojih su pojedine korisni indikatori starosti i metalčnosti, koje takođe predstavljaju fundamentalne osobine galaksija. U krajnjoj statističkoj analizi, ispostavlja se da metalčnost nema značajnu ulogu, dok se uključivanjem starosti galaksija u analizu bitno menjaju rezultati.

Poslednji korak u izboru parametara, predstavlja modelovanje površinskog sjaja galaksija Sersikovim zakonom, koje je u ovoj disertaciji urađeno pomoću programa Galfit. Izračunata disperzija brzina zvezda, zajedno sa dobijenim Sersikovim indeksom i efektivnim radijusom Sersikovog modela ulazi u izračunavanje dinamičke mase, fundamentalne osobine galaksija, korišćene u krajnjoj statističkoj analizi. Na kraju, iz radio-spektroskopije, preuzeta je masa gasne komponente i maksimalna rotaciona brzina, a iz ultraljubičaste/optičke/infracrvene fotometrije (GALEX/SDSS/2MASS baze podataka), preuzete su Kronove magnitude, odnosno boje. Nakon testiranja, za krajnju statističku analizu odabrana je boja izračunata pomoću ultraljubičaste i optičke magnitude ($NUV - r$ boja). Ističemo da ranije analize prostora galaktičkih parametara nisu uključivale disperziju brzina, kao ni boju koja sadrži ultraljubičastu komponentu, iako je ona indikator specifične stope formiranja zvezda u galaksiji. Ova boja doprinosi jačini korelacija među analiziranim parametrima i pokazala se značajnijom od optičkih boja.

Na konačan skup parametara (disperzija brzina, boja, luminoznost, Petrosijanovi radijusi R_{50} i R_{90} , dinamička masa, masa zvezdane i gasne komponente, starost galaksija i maksimalna rotaciona brzina) primenjena je korelaciona analiza koja ispituje korelacije među parametrima. Ovom analizom potvrđene su već poznate korelacije. Zatim je primenjena metoda osnovnih komponenata (engl. principal component analysis) sa ciljem da se nađe i identifikuje najmanji broj komponenata odgovornih za ustrojstvo galaksija, kakvo vidimo danas.

Rezultati statističke analize su sledeći: postoje najmanje tri statistički značajne, nezavisne komponente skupa parametara. Prva i najznačajnija komponenta, ne može se identifikovati ni sa jednom od osobina galaksija, ali joj u podjednako meri doprinose: dinamička masa, masa gasne i zvezdane komponente, luminoznost i Petrosijanovi radijusi R_{50} i R_{90} . Oslanjajući se na prethodne radove slične tematike, ovu komponentu možemo identifikovati sa “veličinom” galaksija. Drugu komponentu, kojoj najviše doprinosi boja, možemo identifikovati sa “izgledom” galaksija. Ona u dosadašnjim radovima nije bila statistički značajna. Treća komponenta može se identifikovati sa starošću galaksija. Postoji indikacija o četvrtoj komponenti kojom dominira maksimalna rotaciona brzina i koja se može identifikovati sa specifičnim ugaonim momentom galaksija. Iako nije statistički značajna, moguće je da će to postati u nekom većem uzorku galaksija, koji bi raspolagao informacijom o pravoj maksimalnoj rotacionoj brzini, pošto jednosnopovski profili HI linija mogu imati samo jedan maksimum i to ne mora biti pravi maksimum. Takođe, maksimalna rotaciona brzina izvedena iz širine HI linije uključuje korekciju za inklinaciju, što je još jedan nepouzdan parametar u analizi.

Dakle, zaključak je da postoje *najmanje tri*, a moguće je i četiri dimenzije višedimenzionalnog prostora parametara, koji u potpunosti opisuju galaksije kakve vidimo danas.

Spectroscopical and photometrical analysis of nearby galaxies of different morphological types

Abstract

The goal of this thesis is to reduce multidimensional space of galactic properties to the smallest number of dimensions sufficient to describe them. For this purpose, the statistical analysis is applied over the parameters that describe fundamental galactic properties on the morphologically representative sample of 2180 galaxies. The sample of galaxies used in this thesis is based on the *Arecibo Legacy Fast ALFA* (Alfalfa) blind HI survey.

The importance of an HI blind survey lies in the fact that galaxies are chosen on the basis of their gas content (HI) solely, thus free of optical selection effects. From the initial sample counting ~ 10000 galaxies, 2180 of them were chosen, since for this subsample the optical spectroscopy from the *Sloan Digital Sky Survey* (SDSS) was available and moreover the photometry in the UV (*Galaxy Evolution Explorer*, GALEX), and optical (SDSS) to the near-infrared (*Two Micron All Sky Survey*, 2MASS).

Parameters are selected according to the previously established correlations between fundamental galactic properties, relying on the previous work. They are extensively tested and confronted between each other to be chosen from the larger parametric space.

To select parameters, we first measured stellar kinematics using publicly available code (pPXF), and tested both empirical and synthetic stellar libraries. In particular, we have measured the velocity dispersion and the higher moments of the line-of-sight velocity distribution function. This is the largest galaxy sample created so far with detailed stellar kinematics measured including higher moments of the line-of-sight velocity distribution function. The sample size allows statistical tests to be applied to the higher

moment of the velocity distribution function (h_4), with respect to the different groups of morphological galaxy types. Various tests agree with the previous indication that elliptical and lenticular galaxies have the same origin.

Further, we have measured the line strength indices for several absorption lines (Lick indices), since some of them are good proxies to galaxy ages and metallicity, also the fundamental galactic properties. In the final statistical analysis, metallicity proves to be of no importance, but the inclusion of galaxy ages in the analysis, the results change significantly.

The last step in the parameter selection is the modelling of the galaxies' surface brightness profiles with the Sersic profile, that is performed in this thesis with the Galfit code. The velocity dispersion measured, along with the Sersic index and effective radius of the Sersic profile takes the role in the dynamical mass calculation, being the fundamental galactic property and hence used in the final statistical analysis. Finally, we have taken the mass of the gas component and maximal rotational velocity from the radio-spectroscopy and Kron magnitudes (i.e. colours) from the ultraviolet/optical/nearinfrared photometry (GALEX/SDSS/2MASS databases). After extensive testing, we have chosen the colour calculated from ultraviolet and optical magnitudes ($NUV - r$ colour), for the final statistical analysis. It is worth noting that previous analysis of the galactic properties lack velocity dispersion, as well as the colour with the ultraviolet component, although it is a direct proxy to the specific star formation rate in the galaxy. This particular colour makes correlations among analysed parameters stronger and proves to be more important than optical colours.

Finally, when the proper parametric space of galactic properties is formed (velocity dispersion, colour, luminosity, Petrosian radii R_{50} and R_{90} , dynamical, HI and stellar masses, maximal rotational velocity and the galaxy ages), the correlation analysis is performed to inspect correlations between parameters. This analysis confirms relations that are already known to hold. Then the principal component analysis is done with the

purpose of finding and identifying the smallest number of galactic properties responsible for the final products of galaxy evolution, as we see today, in the local Universe.

The results of the corresponding analysis are the following: there are at least three statistically important, independent components. The first and the most important component cannot be identified with either galactic property, but presents the mixture of several properties: dynamical mass, mass of the stellar and gas component, luminosity and Petrosian radii R_{50} and R_{90} . Relying on the previous work, this component may be identified with the "size" of the galaxies. The second component, mostly influenced by the galactic colour, may be identified with the "aspect" of the galaxies. The colour was not found to be important in previous work. The galaxy ages can be identified with the third principal component. There is a hint on the fourth component, dominated by the maximal rotational velocity that can be identified with the specific angular momentum of galaxies. Although not proven to be statistically important, it may become so in the larger sample of galaxies which will provide the information of the true peak of the galaxies' rotational curves, since the single-beam HI spectra may show the single maximum and this may not be the true maximum. Also, the rotational velocity includes the inclination correction, another questionable parameter in the analysis.

To conclude: there are *at least three*, and possibly four dimensions of the multidimensional galactic space, as we see today.

Uvod

Rane studije galaksija u radio-oblasti talasnih dužina (Karachentseva, 1973; Solanes et al., 1996) bile su zasnovane na heterogenim uzorcima galaksija, prikupljenim iz različitih izvora i dodatno opterećene selekcionim efektima vidljivog zračenja i malim brojem galaksija. Naime, zbog niske osjetljivosti 21 cm detektora, bilo je potrebno puno vremena za uspješnu (vizuelnu) identifikaciju objekata i zato su mete posmatranja bile unapred poznate. Ovo su u suštini bili optički pregledi, jer su posmatrani objekti birani na osnovu luminoznosti u optičkom delu spektra. Značaj pregleda neba "naslepo" (engl. blind surveys) na liniji neutralnog vodonika, koji selektuje galaksije samo na osnovu sadržaja gasa, a ne optičke luminoznosti je veliki za statističku analizu osobina galaksija. Naime, ovakav uzorak galaksija je reprezentativan u morfološkom smislu u lokalnom Univerzumu.

U pionirskim radovima analize prostora fundamentalnih osobina galaksija u radio-domeni (Brosche (1973), Whitmore (1984)), formiranje uzorka galaksija je bilo inicirano optičkim posmatranjima, te su galaksije iz uzorka bile prevashodno masivne spiralne galaksije. Nasuprot tome, u HI pregledu neba naslepo, galaksije su selektovane isključivo na osnovu sadržaja atomskog gasa, a ne optičke luminoznosti. Veliki uzorak sačinjen iz jednog izvora (*homogeni uzorak*), oslobođen optičkih selekcionih efekata (zasnovan na

prisustvu atomskog gasa) pruža osnovu za statističku analizu, čiji će zaključci biti validni u lokalnom Univerzumu.

Ipak, značajno je pomenuti pionirske rezultate radio-astronomije, među kojima se ističe zaključak do kojeg je došla Karachentseva (1973) na uzorku od 288 objekata, da je nezavisno od morfološkog tipa galaksije, optički izofotalni linearni dijametar meren na izofoti površinskog sjaja 25 mag/''^2 (R_{25}), najvažnija dijagnostička alatka za opisivanje mase neutralnog gasa. Danas je moguće, zahvaljujući boljim detektorima, sačiniti veliki homogeni uzorak galaksija oslobođen optičkih selekcionih efekata, pošto se može snimiti celo nebo na 21 cm liniji, odnosno sve prisutne galaksije isključivo na osnovu sadržaja atomskog gasa.

1.1 HI pregled neba naslepo

Linija neutralnog vodonika (21 cm) prikazuje galaksiju nezavisno od njene zvezdane komponente. Zvezde su nosioci celokupnog vidljivog zračenja, a indirektno učestvuju u nastanku celokupne emisije u celom opsegu spektra vidljivog zračenja. Na primer, emisija čestica prašine u dalekom infracrvenom delu spektra indukovana je zračenjem zvezda, a i ove same čestice prašine nastale su u procesu nukleosinteze ranijih generacija zvezda. I za svaki drugi oblik zračenja (kontinuum i linije) odgovorne su zvezde u nekom stadijumu svoje evolucije, neposredno ili posredno. Suprotno ovome, neutralni vodonik je primordijalan, a 21 cm linija ima tako nisku temperaturu ekscitacije, da je pozadinsko jonizujuće zračenje dovoljno da ga održi pobuđenog. Iako masa atomskog vodonika (HI) ne daje značajan doprinos ukupnoj masi ($\sim 1\%$), rotacija gasa posledica je raspodele ukupne mase i to kako vidljive, tako i nevidljive.

Poslednjih godina, unapređeni višesnopolovski (engl. multi-beam) sistemi omogućili su preglede neba naslepo u radio-oblasti, pokrivanjem velikih površina neba, sa kratkim vremenom ekspozicije i prostornom preciznošću uporedivom sa optičkom, čime je iden-

tifikacija HI objekata u optičkom delu spektra postala trivijalna. Radio pregled prve generacije *HI Parkes All Sky Survey* (HIPASS; Meyer et al. (2004)), pokrio je $\sim 30\,000$ kvadratnih stepeni (deg^2) neba (uključujući celu južnu hemisferu) i detektovao 5317 izvora. Veličina ove baze podataka, omogućila je prvo merenje brojne gustine galaksija u funkciji njihove HI mase (engl. HI mass function) i u funkciji širine HI linije (engl. velocity width function), kao i ispitivanje osnovnih osobina grupisanja (engl. clustering properties). Zbog niske osetljivosti (srednja radijalna brzina galaksija $cz \approx 2500 \text{ km/s}$ ¹), ovaj HI pregled bio je ograničen na lokalni svemir i skroman broj detektovanih izvora malih HI masa (nema HIPASS galaksija sa $M_{\text{HI}} < 10^7 M_{\odot}$). Sa druge strane, *Arecibo Legacy Fast ALFA* (ALFALFA; Giovanelli et al., 2005) pregled uspešno se izborio sa ovim ograničenjima i sačinio najveću bazu galaksija bogatih gasom. ALFALFA pregled izvršen je 305-metarskim Arecibo radio-teleskopom u periodu od 2005. do 2012. godine i, iako pokriva nominalno manju zapreminu (7000 deg^2) od HIPASS-a, zahvaljujući većoj osetljivosti snimio je za red veličine više objekata. Takođe, zahvaljujući boljim performansama, detektovao je značajan broj galaksija veoma malih masa gasa ($M_{\text{HI}} < 10^7 M_{\odot}$) i tako stvorio osnovu za studiju galaksija malih masa.

ALFALFA je dakle, najveći i najpotpuniji HI pregled neba do sada. Mapirao je u 21 cm liniji i detektovao blizu 30 000 radio izvora sa daleko većom ugaonom (FWHM ~ 3.5) i spektralnom ($\sim 5.5 \text{ km/s}$) rezolucijom, nego bilo koji raniji pregled ove vrste. Poređenja radi, dok je HIPASS detektovao jednu galaksiju na svakih 5 kvadratnih stepeni, ALFALFA detektuje oko 5 galaksija po kvadratnom stepenu. Nedavno je postao dostupan ALFALFA katalog koji sadrži 70% pregleda i potpun (100%) katalog u najbližoj okolini ($cz < 3200 \text{ km/s}$). Iz HI spektra mogu se izmeriti sledeći parametri: crveni pomak galaksije, ukupni HI fluks F_{HI} i širina same HI linije na polovini maksimalne vrednosti

¹Pomeraj spektralnih linija galaksije zbir je dva efekta: Doplerovog kretanja koji nastaje usled gravitacionih interakcija i širenja svemira. Iako se ove dve pojave ne mogu razlučiti, termin radijalna brzina odnosi se na Doplerovo kretanje i značajna je u lokalnom Univerzumu, dok je crveni pomak vezan za kosmološke efekte.

fluksa w_{50} . Iz ukupnog fluksa F_{HI} , može se dobiti masa gasne komponente M_{HI} :

$$M_{\text{HI}} = 2.356 \times 10^5 d F_{\text{HI}}, \quad (1.1.1)$$

gde je d rastojanje do galaksije u Mpc, a ukupni fluks F_{HI} izražen u jedinicama Jy km/s. Daljine su izračunate prema modelu toka sopstvenih brzina² (engl. peculiar velocity flow model; Masters (2005)) za bliske galaksije i Hablovom zakonu za udaljene galaksije ($cz > 6000$ km/s). Iz širine HI linije w_{50} , može se izračunati maksimalna rotaciona brzina galaksija:

$$V_r = wc_{50}/(2 * \sin(i)), \quad (1.1.2)$$

gde je i inklinacija galaksije, $wc_{50} = w_{50}/(1 + z)$ širina HI linije korigovana za efekat Doplerovog širenja, a z crveni pomak galaksije. Dakle, masa gasa M_{HI} i maksimalna rotaciona brzina V_r su parametri dostupni iz ALFALFA pregleda.

1.2 Uzorak galaksija

U ovoj tezi korišćen je katalog galaksija zasnovan na približno 40% pregledanog neba iz ALFALFA pregleda, nazvan $\alpha.40$ katalog (Haynes et al., 2011). Ovaj katalog je ukršten sa SDSS³ DR7 spektroskopskim katalogom (3800 – 9200 Å), kako bi se dobili spektri, pomoću kojih će biti izmerene disperzije brzina galaksija i jačine spektralnih linija. Takođe, za sve galaksije iz uzorka dostupna je i optička fotometrija iz SDSS DR8⁴, potrebna za analizu površinskog sjaja galaksija. Zatim je dobijeni katalog ukršten sa

²Model toka sopstvenih brzina zasniva izračunavanje brzina galaksija uzimajući u obzir značajne gravitacione mase u lokalnom Univerzumu (Virgo jato, Veliki atraktor i Lokalna grupa galaksija).

³Sloan Digital Sky Survey, skraćeno SDSS (<http://www.sdss.org>) je optički pregled jedne trećine neba u pet filtera: u (3543 Å), g (4770 Å), r (6231 Å), i (7625 Å) i z (9134 Å). Uporedo sa fotometrijom, snimljeni su spektri za više od tri miliona astronomskih objekata.

⁴Fotometrija je preuzeta iz baze podataka DR8, pošto su slike iz počev od DR8 dostupne bez pozadine. Oduzimanje pozadine je složen problem i nije rađen u ovoj tezi.

GALEX⁵ i 2MASS⁶ fotometrijskim katalogzima kako bi se dodala višetalasna priroda galaksija njihovoj radio-komponenti i to pre svega boja $NUV - r$, koja je indikator specifične stope formiranja zvezda (Salim, 2014). Iz $\alpha.40$ kataloga, u tezi su korišćene vrednosti M_{HI} i V_r . Iz optičkih spektara (SDSS DR7), izmerene su disperzije brzina i jačine apsorpcionih linija, koje su dobri indikatori starosti i metaličnosti. Iz GALEX i 2MASS baza podataka, preuzete su Kronove magnitude (Kron, 1980)⁷ u svim dostupnim filterima: NUV i FUV (GALEX) i J, H, K_s (2MASS). U SDSS DR8 fotometrijskom katalogu, identifikovani su svi objekti i preuzete su njihove slike u r filteru. One će biti korišćene za modelovanje površinskog sjaja galaksija. Iz istog kataloga, biće korišćene Petrosijanove magnitude g i r , čija razlika daje boju $g - r$ i Petrosijanovi radijusi R_{50} i R_{90} , koji obuhvataju 50% i 90% ukupnog fluksa galaksije, redom. Petrosijanove magnitude mere konstantan udeo sjaja u ukupnom sjaju galaksije i nezavisne su od daljine objekta. Petrosijanov radijus R_P je radijus unutar kojeg je lokalni (azimutalno usrednjeni) profil površinskog sjaja galaksije jednak 20% srednjeg sjaja unutar istog radijusa (Blanton et al., 2001):

$$0.2 = \frac{2\pi \int_{0.8R_P}^{1.25R_P} [I(r)rdr]/[\pi r^2(1.25^2 - 0.8^2)]}{2\pi \int_0^{R_P} [I(r)rdr]/[\pi r^2]}, \quad (1.2.1)$$

gde je $I(r)$ azimutalno usrednjeni profil sjaja galaksije. Petrosijanov fluks je definisan kao ukupni fluks unutar radijusa $2R_P$. Unutar ovog radijusa meri se uvek isti deo ukupnog fluksa, nezavisno od daljine objekta. Detaljan opis pretraživanja baza podataka, radi kreiranja uzorka galaksija dat je u Dodatku A.

⁵Galaxy Evolution Explorer, skraćeno GALEX (<https://galex.stsci.edu/GR6/>) je pregled neba u ultraljubičastom delu spektra u dva filtera: NUV (2267 Å) i FUV (1516 Å).

⁶The Two Micron All Sky Survey, skraćeno 2MASS (<http://www.ipac.caltech.edu/2mass/>) je pregled celog neba u bliskom infracrvenom delu spektra u tri filtera: J (1.25 μm), H (1.65 μm) i K_s (2.17 μm).

⁷Kronove magnitude odgovaraju fluksu merenom unutar eliptične aperture skalirane tako da bude 2.5 puta veća od prvog momenta raspodele površinskog sjaja galaksije.

1.3 Prostor analiziranih parametara

Toribio et al. (2011) sproveli su statističku analizu na 1624 objekta iz ALFALFA pregleda, upotpunjenim optičkim bojama galaksija kako bi identifikovali jedinstvene parametre koji najjasnije definišu sadržaj gasa u galaksijama, ali i istražili relacije skaliranja među veličinama koje su snažno korelisane sa HI masom. Koristeći pet osobina galaksija: masu atomskog gasa (M_{HI}), širinu HI linije na polovini najveće vrednosti fluksa HI linije (w_{50}), radijus meren na 25 mag/''² (R_{25}), apsolutnu optičku magnitudu u r filteru (M_r) i optičku boju ($g - r$), oni nalaze tri značajne nezavisne relacije među njima (koje objašnjavaju 99.05% varijanse sistema). Zaključci studije su sledeći: (i) HI emiteri pokazuju visok stepen korelacije u smislu da navedeni parametri jako korelišu međusobno i sa masom atomskog gasa sugerišući da su HI emiteri jednoparametarska familija; (ii) najbolji pokazatelj očekivane vrednosti mase neutralnog gasa (M_{HI}) je izofotalni linearni dijametar R_{25} ; (iii) tzv. morfološki pokazatelji kao što je boja galaksija, slabo korelišu sa gasnom komponentom.

Proširujući parametarski prostor iz rada Toribio et al. (2011) uvođenjem spektroskopskih parametara (disperzije brzina i starosti galaksija⁸), polazeći od uzorka koji broji 2180 galaksija u okruženjima različitih gustina, usamljenih i grupisanih galaksija svih morfoloških tipova (engl. field and clustered galaxies), sa informacijom o maksimalnoj rotacionoj brzini i HI masi (iz radio-oblasti) iz *homogenog* uzorka, dopunjenih ultraljubičastim, optičkim i bliskim infracrvenim magnitudama, ponovljena je korelaciona analiza upotpunjena analizom osnovnih komponenata (šesto poglavlje). Konačan skup analiziranih parametara broji 10 parametara i to su: Petrosijanovi radijusi R_{50} i R_{90} , masa zvezdane i gasne komponente M_k i M_{HI} , disperzija brzina σ , maksimalna rotaciona brzina V_r , luminoznost u g filteru L_g , starost i $NUV - r$ boja.

Akcent u ovoj tezi stavljen je na ispitivanje uzorka iz jednog izvora ($\alpha.40$ kataloga), koji ga čini homogenim u smislu da su mereni parametri (maksimalna rotaciona brzina i

⁸Starost galaksija može se odrediti i fotometrijski, spektroskopski metod je samo jedan od postojećih.

masa atomskog gasa) dobijeni korišćenjem istog radio-teleskopa, tako što su radio-spektri obrađeni na isti način, a parametri izmereni istim postupkom. Suprotno, heterogeni uzorak sastavljen je iz različitih kataloga, što ga čini podložnim sistematskim greškama. Još jednom treba napomenuti i značaj HI pregleda naslepo, koji ne selektuje galaksije na osnovu njihove optičke luminoznosti, već isključivo prema sadržaju atomskog gasa. Ovakav pregled, za razliku od optičkog, može detektovati i galaksije nevidljive u optičkom delu spektra, jer ne poseduju dovoljan broj zvezda da bi bile vidljive, tzv. tamne galaskije. Detekcija tamnih galaksija je značajna za kosmologiju pošto Λ CDM teorija predviđa postojanje velikog broja ovakvih galaksija. Pa ipak, detektovano je svega 2% galaksija koje nemaju optički pandan i to prevashodno u spoljnim delovima jata galaksija, te su najverovatnije u pitanju ostaci sudara galaksija, preciznije gas izbačen iz galaksija prilikom sudara.⁹

Nameće se pitanje da li je ovakav uzorak reprezentativan u morfološkom smislu, pošto galaksije ranog tipa sadrže veoma malo gasa. Serra et al. (2010) ispituju sadržaj atomskog gasa u galaksijama ranog tipa unutar i izvan Virgo jata galaksija i zaključuju da je HI gas uobičajen i u ovakvim galaksijama, osim u onima koje se nalaze u najgušćim oblastima u smislu koncentracije galaksija (u centralnim delovima jata). Detaljan opis uzorka galaksija korišćen u ovoj tezi, dat je u drugom poglavlju.

1.4 Kinematika galaksija

Raspodela brzina zvezda u galaksiji, projektovana na pravac posmatranja, može se opisati Gausovom funkcijom sa višim momentima, odgovornim za odstupanje od Gausijana. U ovoj tezi izračunat je kinematički profil uključujući više momente na najvećem uzorku galaksija do sada. Naime, postoje dva uzorka galaksija za koje je izmerena kompletna kinematika zvezda (uključujući više momente) i to su: *ATLAS*^{3D} (Cappellari et al.,

⁹<http://egg.astro.cornell.edu/index.php/>.

2011) i *Hobby–Eberly Telescope Massive Galaxy Survey (HETMGS)* (van den Bosch et al., 2015). Oba ova uzorka su manja i nisu morfološki reprezentativna: *ATLAS*^{3D} obuhvata samo galaksije ranog tipa, a *HETMGS* galaksije velikih disperzija, pogodnih za računanje masa crnih rupa, što je i bio cilj ovog projekta. Uzorak galaksija analiziran u ovoj tezi, sa druge strane, oslikava lokalnu morfološku distribuciju galaksija, pošto je sačinjen iz HI pregleda naslepo i omogućava sprovođenje statističke analize viših momenata raspodele brzina zvezda.

Posebno, razmotrene su i implikacije pojednostavljivanja funkcije raspodele brzina zvezda Gausovom funkcijom. Takođe, uzimajući u obzir greške kinematičkih parametara, posebno viših momenata, ispitano je koliki je odnos signala prema šumu potrebno dostići, da bi negausovska korekcija bila značajna. Svakako značajniji efekat od negausovskih korekcija ima izbor zvezdane biblioteke, pomoću koje se izračunava kinematika. Testirani su sintetički (modelovani) i empirijski (posmatrani) zvezdani spektri, koji služe kao osnova za merenje kinematike, upoređeni su međusobno i posebno sa nezavisnim izvorom kinematike.

1.5 Starost i metaličnost galaksija

Zvezdana populacija (engl. stellar population) je skup zvezda sličnog hemijskog sastava i starosti. Cilj modela sinteze zvezdane populacije (engl. stellar population synthesis models) jeste da odredi najznačajnije parametre zvezdane populacije: starost i metaličnost poredeći posmatrane boje ili jačine apsorpcionih linija (engl. line strength indices) sa modelima. Zašto je ovo važno?

Postoje dva sučeljena scenarija nastanka galaksija: hijerarhijski model i monolitni kolaps. Naime, hijerarhijski model predviđa da su galaksije nastale sudarima manjih galaksija i posebno da su eliptične galaksije nastale sudarima diskova (Mo et al. (2010)). Sa druge strane, monolitni kolaps (Eggen et al., 1962) predviđa da su galaksije nastale

”trenutno”, kad je primordijalni oblak gasa kolapsirao pod dejstvom gravitacije, odnosno da su svi delovi galaksije iste starosti. Ovaj model je opovrgnut na dva fronta: ustanovljene su razlike u starosti između različitih delova (bliskih) galaksija i prihvaćena je Λ CDM ($\Lambda + \text{CDM}$) kosmologija¹⁰ koja predviđa nastanak većih struktura iz manjih (engl. bottom-up), nalik hijerarhijskom modelu.

Modeli nastanka galaksija mogu se ispitati studiranjem njihovih zvezdanih populacija, koje predstavljaju krajnji rezultat hemijske evolucije i istorije nastanka zvezda (engl. star formation history). Problemi hijerarhijskog modela su mnogobrojni: postojanje relacija skaliranja sa vrlo malo rasipanja, kao što je boja-magnituda (engl. color-magnitude relation) relacija, fundamentalna ravan (engl. fundamental plane; Djorgovski & Davis (1987)) itd. Štaviše, boja-magnituda relacija potvrđena je na crvenom pomaku $z \sim 1.24$ (Blakeslee et al., 2003). Zatim, veće galaksije pokazuju veću srednju starost od manjih galaksija (Kauffmann et al., 2003). Takođe, bliske džinovske eliptične galaksije pokazuju obogaćenje [Mg/Fe] elementima (Baugh et al., 1996). Svi ovi dokazi ukazuju na to da se većina zvezda u eliptičnim galaksijama formirala veoma rano, što je u suprotnosti sa hijerarhijskim modelom nastanka galaksija.¹¹

Dakle, značajno je odrediti starost galaksija i to duž morfološkog niza, kako bi se moglo ustanoviti na koji način su galaksije različitih tipova nastale i kada. Postoje dva načina da se iz posmatranih veličina odredi starost galaksija: fotometrijski (iz boja) i spektroskopski (iz jačine apsorpcionih linija ili modelovanjem celih spektara). Rani modeli spektralne sinteze pokušali su kombinovanjem zvezda u određenoj proporciji da ”naprave” galaksiju. Nažalost, različite kombinacije zvezda rezultovaće istim integralnim

¹⁰ Λ CDM model je standardan kosmološki model teorije Velikog praska, pošto objašnjava postojanje i strukturu kosmičkog pozadinskog zračenja, kao i raspodelu galaksija na velikim skalama (Peebles, 1982). Model predviđa, pored vidljive materije koja se može detektovati putem zračenja postojanje hladne, tamne materije (engl. cold dark matter, skraćeno CDM) i tamne energije (Λ).

¹¹Za rani prikaz problema hijerarhijskog modela, pogledati Ostriker (1980). Za novi prikaz, kao i za poređenje sa monolitnim kolapsom videti Matteucci (2012), poglavlje 6.

spektrum, te je ovaj metod neinformativan. Zatim se prešlo na kreiranje jedinstvenih zvezdanih populacija (engl. single stellar population, SSP) kao gradivnih blokova galaksija, umesto individualnih zvezda. Ovako se iz zvezdanih biblioteka pomoću modela koji uključuju inicijalnu stopu formiranja zvezda (engl. initial mass function, IMF) i izohrone (putanje u prostoru luminoznosti i temperature zajedničke za zvezde različite mase u istom trenutku, tj. iste starosti) pravi SSP spektar sa velikim opsegom metaličnosti i starosti; svaka tačka na izohroni ima spektar određene temperature, sastava i površinske gravitacije (predstavljajući jednu zvezdu). Izohrona nam govori koju temperaturu i metaličnost da pripišemo određenoj masi. Zatim saberemo spektre svih zvezda, otežane IMF duž izohrone i dobijemo spektar galaksije. I, konačno, moramo uporediti *posmatrane* parametre (boje ili apsorpcione indekse) sa predviđanjima ovakvih modela. Tada nastaju mnogobrojni problemi. Jedan od najvećih problema je degeneracija između starosti i metaličnosti, koja čini da galaksija izgleda crvenije ili zato što je starija ili zato što sadrži više metala. Izmerena boja ne može razlučiti staru galaksiju siromašnu metalima od mlade galaksije bogate metalima. Najveća degeneracija je u optičkom delu spektra, pa čak ni kombinacija dve boje ne može razrešiti degeneraciju. Infracrvene boje su osetljivije na metaličnost, te delom razbijaju degeneraciju, a posebno kombinacija infracrvene i optičke boje. Nažalost, infracrvene boje ovo duguju doprinosu asimptotskih džinovskih zvezda (engl. Asymptotic Giant Branch, AGB) ukupnom spektru, za koje nedostaju teorijski modeli zbog nedovoljnog razumevanja fizike ovih zvezda. Na primer, u modelima Maraston (2005), 80% infracrvene luminoznosti zvezdane populacije starosti 1 Gyr dolazi od AGB zvezda. Dodavanjem ultraljubičastih boja dobija se značajna osetljivost na starost, ali ostaje (manja) degeneracija. Ultraljubičastim zračenjem dominiraju zvezde glavnog niza koje ga tek napuštaju (engl. main sequence turn-off stars). U ultraljubičastom delu spektra su jako sjajne stare zvezde kao *blue horizontal branch* (skraćeno, BHB), *extreme horizontal branch* (skraćeno, EHB) i *blue straggler* (skraćeno, BS), a još ne znamo kako da predvidimo njihovo učešće u datoj zvezdanoj populaciji.

Slika 1.1: Spektri dve galaksije različite starosti i metaličnosti koji deluju identično. Tek se u njihovom količniku mogu uočiti razlike. Na x -osi je talasna dužina u angstromima, a na y -osi fluks.

Moćno oružje za razbijanje degeneracije između starosti i metaličnosti su pojedine apsorpcione linije, odnosno delovi spektra brižljivo odabrani tako da se postigne osetljivost ili na starost ili na metaličnost i izbegne (koliko je moguće) njihova isprepletanost. Na slici 1.1 prikazana su dva gotovo identična spektra različite starosti i metaličnosti i njihov količnik.¹² Tek u tom njihovom količniku pojavljuju se merljive razlike, koje mogu razbiti prisutnu degeneraciju.

U četvrtom poglavlju mereni su tzv. Likovi indeksi (engl. Lick indices; Worthey et al. (1994); Worthey & Ottaviani (1997)). To je skup od 25 spektralnih indeksa, zapravo površina apsorpcionih linija (nalik ekvivalentnoj širini), merenih u određenim delovima spektra, odabranim tako da se postigne osetljivost indeksa ili na starost ili na metaličnost.

¹²<http://astro.dur.ac.uk/~rjsmith/stelpops.2010.lec3.pdf>

Indeksi su mereni programom napisanim u tu svrhu koristeći *Interactive Data Language* (skraćeno, IDL¹³). Posebno je izračunata starost i metaličnost galaksija modelovanjem celog spektralnog opsega galaksija (3800 – 9200)Å, korišćenjem sintetičkih spektara različitih starosti i metaličnosti, pomoću javno dostupnog programa *ulyss* (Koleva et al., 2008, 2009).¹⁴ U prostoru ili mreži (engl. grid) starosti i metaličnosti, metodom interpolacije za svaku galaksiju iz uzorka određena su pomenuta dva parametra (modelovana starost i metaličnost, u daljem tekstu). Likovi indeksi će biti korišćeni u krajnjoj statističkoj analizi, kao indikatori starosti i metaličnosti.

1.6 Površinski sjaj galaksija

Metode morfološke klasifikacije galaksija oslanjaju se na raspodelu površinskog sjaja galaksije. Analiza raspodele sjaja objekata daje parametre pomoću kojih se može napraviti razlika između različitih tipova galaksija. U opštem slučaju, razlikujemo neparametarske i parametarske metode. Neparametarske metode ne pretpostavljaju *a priori* raspodelu površinskog sjaja, dok se parametarske zasnivaju na "zakonima" raspodele sjaja opisane odgovarajućim funkcijama. Najpoznatije neparametarske metode (zasnovane na različitim parametrima) su: indeks koncentracije (Kent, 1985), parametar asimetrije (Abraham et al., 1996), glatkost (engl. smoothness; Conselice et al. (2003)), džini (engl. Gini) koeficijent (Abraham et al., 2003), M_{20} koeficijent (Lotz et al., 2004) i rapavost (engl. coarseness parametar; Yamauchi et al. (2005)). Ipak, nijedna od ovih metoda nije uspešno razdvojila morfološke tipove. Čak ni kombinacijom pomenutih parametara, na primer uzimajući koncentraciju, asimetriju i glatkost (engl. Concentration Assymetry and Smoothness, CAS system) zajedno, ne može se postići više od grube podele galaksija na kanonske tipove (galaksije ranog i kasnog tipa; Cassata et al. (2005)).

Galaksije se u opštem slučaju sastoje od centralnog ovala, diska i haloa. Ovo su

¹³IDL je programski jezik, koji se koristi za analizu podataka: <http://www.harrisgeospatial.com>.

¹⁴<http://ulyss.univ-lyon1.fr>.

strukturno i dinamički različite komponente. Dodatno, galaksije mogu imati prečage (engl. bar), prestenove (engl. ring), spiralne grane (engl. spiral arms) i druge komponente. Imenitelj parametarskih metoda je fitovanje raznih analitičkih modela posmatrane raspodele površinskog sjaja galaksija. Dve osnovne komponente dovoljno sjajne da se mogu modelovati su centralni oval i disk. Dekompozicija na centralni oval i disk je fizički opravdana postojanjem različitih dinamičkih komponenti, intuitivna i omogućava povezivanje izvedenih veličina kao što je odnos centralnog ovala i diska (engl. bulge-to-disk ratio; B/D , nadalje) sa morfologijom galaksija. Površinski sjaj galaksija opada eksponencijalno sa udaljenošću od centra, sa promenljivim stepenom. Ovaj najopštiji analitički oblik raspodele površinskog sjaja, naziva se Sersikovim zakonom (Binney & Merrifield, 1998) i glasi:

$$I(r) = I_e \exp \left\{ b_n \left[\left(\frac{R}{R_e} \right)^{1/n} - 1 \right] \right\}, \quad (1.6.1)$$

gde je I_e fluks unutar efektivnog radijusa R_e (radijus koji obuhvata polovinu ukupnog sjaja galaksije), n Sersikov indeks, a b_n funkcija Sersikovog indeksa ($b_n \approx 2n - 0.396$, za $n > 1$). Variranjem Sersikovog indeksa mogu se opisati različite dinamičke strukture galaksije (slika 1.2). Ukupni fluks galaksije (F_{tot}), dobija se integracijom površinskog sjaja do beskonačnosti ($R = \infty$):

$$F_{\text{tot}} = 2\pi R_e^2 I_e e^{b_n} n b_n^{-2n} \Gamma(2n) q, \quad (1.6.2)$$

gde je $\Gamma(n)$ Γ funkcija Sersikovog indeksa n , a q odnos male i velike poluose galaksije. Postoje specifične vrednosti Sersikovog indeksa, karakteristične za određene dinamičke strukture galaksija:

- $1.5 < n < 10$: klasičan centralni oval
- $1 < n < 2$: pseudo-oval
- $n \sim 1$: disk

Slika 1.2: Sersikov zakon raspodele sjaja galaksija sa promenljivim stepenom n (Sersikovim indeksom). Različite vrednosti stepena odgovaraju različitim dinamičkim strukturama galaksije. Izvor: Peng et al. (2002).

- $n \sim 1.5$: prečaga.

Posebno, kod eliptičnih galaksija, ali i centralnih ovala spiralnih galaksija, površinski sjaj se uobičajeno opisuje Devokulerovim zakonom (engl. de Vaucouleurs law; de Vaucouleurs (1948), što je jedna karakteristična vrednost Sersikovog indeksa $n = 4$.

Prve parametarske metode usrednjavale su sjaj galaksije azimutalno, odnosno tražile izofote (elipse istog sjaja) kojima odgovaraju određene vrednosti eliptičnosti (odnosa male i velike poluose elipse), pozicionog ugla i centra galaksije. Svi ovi parametri mogu varirati od centra galaksije ka periferiji (Jedrzejewski, 1987). Međutim, ozbiljan nedostatak ovakvih metoda leži u činjenici da mnoge galaksije imaju više od dve komponente (prečagu, jezgro, spiralne grane); pa čak i kada su dvokomponentni sistemi, eliptičnost i pozicioni ugao mogu se menjati sa udaljenošću od centra galaksije kod svake komponente različito. Kako bi se prevazišla ovakva ograničenja, razvijeno je dvodimenzionalno modelovanje površinskog sjaja galaksija (Peng et al., 2002). Ovakvo modelovanje uzima u obzir sjaj cele galaksije u dve dimenzije, onako kako se vidi na slici. Višestruke strukture mogu se izdvojiti i fitovati istovremeno (npr. centralni oval

+ prečaga + disk), ali pošto imaju veći broj parametara, može se javiti degeneracija među parametrima. Vrednosti modelovanih parametara mogu se dovesti u vezu sa morfologijom galaksija. Ravindranath et al. (2004) i Barden et al. (2005) predložili su klasifikaciju zasnovanu na Sersikovom indeksu, tako da se mogu razlikovati "sferoidne" galaksije ($n > 2.5$) i galaksije kasnog tipa ($n < 2.5$). Cassata et al. (2005) i Sargent et al. (2007), pokazali su da je klasifikacija pomoću odnosa B/D daleko pouzdanija od Sersikovog indeksa.

U petom poglavlju urađeno je modelovanje površinskog sjaja galaksije Sersikovom funkcijom (1.6.1), pomoću javno dostupnog programa Galfit¹⁵ (Peng et al., 2002). Na ovaj način dobijena su dva značajna parametra za dalju analizu: Sersikov indeks i efektivni radijus. Obe veličine ulaze u izraz za dinamičku masu, koja će kao još jedna fundamentalna osobina galaksija biti korišćena u krajnjoj statističkoj analizi.

1.7 Statistička metoda osnovnih komponenta

Jedan od glavnih ciljeva ove teze je pronalaženje najmanjeg broja (nezavisnih) parametara koji definišu integralne osobine galaksija, primenjujući metodu osnovnih komponenta (engl. principal component analysis, u daljem tekstu PCA metoda; Venables & Ripley (2002)) na veliki broj galaksija iz *homogenog* uzorka, oslobođenog optičkih selekcionih efekata.

U originalnom prostoru merenih parametara $(x_1, x_2 \dots x_n)$, "oblak" od N galaksija se smešta u standardizovanu formu sa nultom srednjom vrednošću i jediničnom varijansom.¹⁶ Na ovaj način centar koordinatnog sistema parametara postaje centar inercije "oblaka", pri čemu svaka tačka ima jednaku težinu $1/N$. Metoda osnovnih komponenta omogućava nalaženje novih koordinatnih osa $(\zeta_1, \zeta_2 \dots \zeta_n)$ koje su ortogonalne, odnosno

¹⁵<https://users.obs.carnegiescience.edu/peng/work/galfit/galfit.html>.

¹⁶Svaka promenljiva je normalizovana, tako što joj se oduzima srednja vrednost i zatim se deli standardnom devijacijom. Greške se mogu uračunati prilikom normalizacije.

statistički nezavisne (nekorelisane) i koje su povezane sa originalnim parametrima (x_k) linearnom transformacijom:

$$x_k = F(k, 1)\zeta_1 + F(k, 2)\zeta_2 + \dots + F(k, n)\zeta_n. \quad (1.7.1)$$

Transformacija $F(k, i)$, gde je $i = 1 \dots n$ je ortogonalna i jednaka rotaciji koordinatnog sistema. Nove koordinatne ose su sopstveni vektori korelacione matrice problema i predstavljaju komponente koje PCA metoda pronalazi. Sopstvene vrednosti ($\lambda_1 > \lambda_2 > \dots > \lambda_n$) formiraju "osnovnu" (engl. principal) dijagonalu transformisane kovarijantne matrice i predstavljaju varijanse parametara ζ_j . Samim tim, parametar koji odgovara najvećoj sopstvenoj vrednosti λ_1 , odgovara i najvećoj komponenti varijanse, koji PCA metoda treba da pronađe. To je zapravo osa sa najmanjom sumom kvadrata ortogonalnih odstupanja individualnih tačaka. Dakle, veličina svake sopstvene vrednosti je mera relativnog doprinosa njoj odgovarajućeg parametra ζ ukupnoj varijansi sistema¹⁷. Odbacivanjem onih parametara čiji je doprinos ukupnoj varijansi zanemarljiv, mogu se naći prave dimenzije sistema ($\zeta_1, \zeta_2 \dots \zeta_s, s < n$). S obzirom na to da je u osnovi metode traženje linearnih relacija među parametrima, zahteva se da ulazni parametri zavise linearno jedni od drugih.¹⁸ Nova dimenzionalnost je manja od originalne i najčešće se uzima prema "teoremi donje granice" (Guttman, 1954) da su značajne one sopstvene vrednosti veće od jedinice. Na kraju, metoda će biti uspešna koliko su dobri podaci.

Metod je prvi put primenjen davne 1973. godine na *spiralnim* galaksijama koje su imale merene rotacione krive u pionirskom radu Brosche (1973), kada je ustanovljeno postojanje *dve značajne dimenzije* (dve ortogonalne koordinatne ose ili osnovne kom-

¹⁷Varijansa sistema je kvadratno odstupanje (kvadratni stepen devijacije) vrednosti parametara u odnosu na koordinatne ose sistema koji kreira statistička analiza. U slučaju dva parametra, linearna metoda najmanjih kvadrata daje najmanje kvadratno odstupanje tačaka od linije fita, odnosno ima najmanju varijansu. Sa druge strane, može se reći da ova linearna funkcija prati najveću strukturu promenu raspodele tačaka. U PCA metodi, za ovakav vektor kaže se da objašnjava najveću varijansu.

¹⁸Potrebno je uzeti logaritme veličina koje su vezane stepenim zakonima.

ponente) između sedam promjenljivih: morfološki tip, maksimalna vrednost rotacione krive, radijus na kome rotaciona kriva postaje maksimalna, fotometrijski dijаметar, luminoznost, indeks boje i masa neutralnog vodonika. Pomoću samo dve dimenzije koje se nisu mogle identifikovati ni sa jednim od ulaznih parametara, objašnjeno je 83% varijanse sistema. Njihovi rezultati potvrđeni su 1981. godine radom Bujarrabal et al. (1981) na tri kataloga od po 100 normalnih galaksija. Ustanovljeno je da se 87% varijanse može opisati pomoću dve osnovne komponente. Dve dimenzije su identifikovane kao "veličina" galaksija (luminoznost, masa, dijаметar) i "izgled" (indeks boje i morfološki tip). Nešto kasnije, Whitmore (1984) potvrđuje da se 85% varijanse nalazi u dve dimenzije i predlaže dvodimenzionalni sistem klasifikacije zasnovan na "skali" (kombinaciji apsolutne plave luminoznosti i apsolutnog radijusa na izofoti sjaja 25 mag/arcsec^2) i "izgledu" (kombinaciji $B - H$ boje¹⁹ i odnosa sjaja centralnog ovala prema ukupnom sjaju galaksije). Svi ovi radovi tretiraju *spiralne* galaksije u malom broju iz *heterogenih* uzoraka koji su, dakle, podložni selekcionim efektima.

Do izvesnog napretka došlo je sa prvim HI pregledima, kao što je HIPASS (Meyer et al., 2004), koje mapirao celu južnu hemisferu na frekvenciji od 21 cm *nezavisno od optičkog sjaja galaksija, uzimajući u obzir samo njihov sadržaj gasa*. Koristeći po prvi put *homogene* podatke²⁰, Disney et al. (2008) su kombinovanjem HI podataka i optičkih (SDSS) merenja došli do nagoveštaja da sve galaksije, nezavisno od morfologije, leže na jedinstvenoj fundamentalnoj pravoj (dakle, ne ravni, već pravoj), sugerišući postojanje jedinstvenog parametra odgovornog za nastanak i evoluciju galaksija. Disney et al. (2008) su sastavili uzorak od svega 195 galaksija, koristeći HIPASS pregled, što je za red veličine manji uzorak od ovde korišćenog.²¹ Autori analiziraju šest parametara: dinamičku masu

¹⁹Indeks boje dobijen je razlikom plave (B) i infracrvene (H) magnituda, koje su u radu Whitmore (1984) preuzete iz kataloga *The Second Reference Catalogue* (RC2); de Vaucouleurs et al. (1976).

²⁰Homogeni podaci ovde su podaci iz jednog izvora, za razliku od heterogenih podataka sakupljenih iz različitih izvora, različite tačnosti, obrađenih na različite načine.

²¹U prepisci sa prvim autorom pomenutog rada (Disney et al., 2008) 2009. godine, nismo dobili

M_{dyn} , masu gasa M_{HI} , luminoznost L_g , Petrosijanove radijuse R_{50} i R_{90} i boju $g - r$. Ipak, iako je samo prva sopstvena vrednost veća od 1.0 i samim tim statistički značajna, druga sopstvena vrednost jednaka je 0.7, ali je nezavisna od svih drugih parametara i iz ovog razloga, smatraju autori, treba je uzeti u obzir. U pitanju je optička boja $g - r$ (razlika magnituda u filteru g i r). Na značajno većem uzorku galaksija iz ALFALFA pregleda (osam puta većem), Toribio et al. (2011) nalazi da optička boja, kao posledica grešaka marenja u velikoj meri koreliše sa drugom osnovnom komponentom. Naime, kada se merenja koriguju uzimajući u obzir greške posmatranja, boja više nije dominantna komponenta drugog sopstvenog vektora, čija je sopstvena vrednost manja od 1.0. Samo prva sopstvena komponenta, sa sopstvenom vrednošću $\lambda \approx 4$ objašnjava 83% varijanse sistema. Nadovezujući se na ovaj rad, Chang et al. (2012) dodaje infracrvenu boju $i - J$ iz 2MASS baze podataka. Kao motivaciju navodi manju osetljivost boje u infracrvenom delu spektra na mlade zvezde, koje dominiraju galaksijama iz uzorka. Konačni uzorak ima 479 galaksija i testiran je sa optičkom $g - r$ bojom i posebno sa bliskom infracrvenom $i - J$ bojom. U prvom slučaju, optička boja zaista dominira drugim sopstvenim vektorom ali nije statistički značajna ($\lambda < 1$), dok u drugom slučaju infracrvena boja čini drugu komponentu i statistički je značajna ($\lambda = 1$). Interesantno je još da infracrvena boja, za razliku od optičke ne koreliše sa ostalim parametrima. Prva komponenta objašnjava 76% varijanse, a kada se doda druga komponenta ukupna varijansa koja se može objasniti je 85%.

Sinergija fundamentalnih osobina galaksija u reprezentativnom uzorku u pogledu njihove morfologije, oslobođenom optičkih selekcionih efekta, mogla bi da rezultira jasnijom slikom nastanka i evolucije galaksija, posmatrajući statistički značajan uzorak u lokalnom Univerzumu. Potrebno je još jednom napomenuti da optički pregledi neba, kakav je SDSS detektuju galaksije na osnovu njihovog sjaja u optičkom delu spektra (optički selekcionni efekti), dok HI pregledi detektuju galaksije isključivo na osnovu sadržaja atomskog gasa

informaciju o tome koje tačno galaksije su analizirane niti kako su pojedini parametri računati.

HI, a nezavisno od sjaja u vizuelnom domenu.

1.8 Fundamentalne osobine galaksija

U opštem slučaju možemo uzeti da su nezavisne invarijantne fizičke osobine galaksija: ukupna masa, udeo bariona, starost, ugaoni momenat, haotična energija, radijus i centralna koncentracija. Kada se galaksija virijalizuje, teorema virijala ostavlja *jednu relaciju* između njih, pri čemu ostaje šest nezavisnih osobina.

Ako zanemarimo interakcije, možemo pretpostaviti da će osobine galaksija biti očuvane. Interakcije između galaksija mogu dovesti do disipacije haotične energije i gubitka određenog dela barionskog sadržaja. Dakle, ostaje *pet korelacija* (između šest nezavisnih parametara), koje ukazuju na visok stepen organizacije među galaksijama. Garcia-Appadoo et al. (2009) nalaze, odnosno potvrđuju pet značajnih korelacija, koristeći devet parametara koji bi mogli u potpunosti opisati galaksiju u smislu strukture, postanka i evolucije: masu neutralnog vodonika (M_{HI}), dinamičku masu (M_{dyn}), površinski sjaj u g filteru (Σ_g), Petrosijanove radijuse koji obuhvataju 50% i 90% ukupnog fluksa galaksije R_{50} i R_{90} ²², luminoznost u g i H filteru (L_g i L_H), širinu HI linije merenu na nivou gde fluks dostiže 20% maksimalne vrednosti (w_{20}) i boju ($g - r$). Oni potvrđuju vezu između površinskog sjaja i luminoznosti, tj. da su galaksije manje luminoznosti slabijeg površinskog sjaja. Iako deluje intuitivno, bilo je potrebno potvrditi ovu relaciju na uzorku bez optičkih selekcionih efekata. Dalje, oni nalaze da je $M_{\text{HI}} \propto R_g^{2*}$, odnosno da je njihov odnos konstantan sugerišući da sve galaksije imaju istu gustinu neutralnog vodonika. Takođe, oni pokazuju da je luminoznost u g filteru (L_g) usko korelisana sa dinamičkom masom i ova korelacija pokazuje manje rasipanje tačaka od *Tully-Fisher*-ove relacije. Koristeći vezu između L_g i L_H ²³ luminoznosti, autori dobijaju da je dinamička

²²Za definiciju pogledati poglavlje 6.1.

*Indeks g označava optički g filter.

²³Luminoznost u bliskom infracrvenom H filteru na talasnoj dužini $\lambda = 2.2\mu\text{m}$.

masa $M_{\text{dyn}} \sim L_{\text{H}}$, odnosno da je odnos mase i sjaja konstantan i isti za sve galaksije u H filteru. Poslednja korelacija između radijusa koji obuhvataju 50% i 90% sjaja galaksije, govori da nezavisno od morfologije, spoljni profili sjaja prate eksponencijalni zakon i takođe, njihov odnos se ne menja sa luminoznošću. Autori razmatraju posebno i izvedene veličine, kao što su specifični ugaoni moment galaksije i njena ukupna energija.

1.9 Novi analizirani parametri

Prethodnoj analizi nedostaje karakterizacija interakcije među galaksijama, koja se može predstaviti preko specifične stope formiranja zvezda. Postojanje korelacije između specifične stope formiranja zvezda i boje sa ultraljubičastom komponentnom $NUV - r$ (Salim, 2014), opravdava uvođenje ultraljubičaste fotometrije (iz GALEX-a) u dalju analizu. Ostaje još pitanje koliko okruženje galaksija utiče na njihovu evoluciju i da li je potrebno uvesti dodatni parametar koji bi mogao da kvantifikuje blizinu galaksija. Međutim, Martin et al. (2012) pokazuju da galaksije iz $\alpha.40$ kataloga praktično nemaju tendenciju grupisanja, odnosno da galaksije bogate HI gasom predstavljaju "skup galaksija najmanje grupisan od svih poznatih populacija galaksija". Samim tim, okruženje ovakvih galaksija ne može imati značajnu ulogu.

Posebno značajan parametar, koji najbolje koreliše sa bojom galaksija, jeste disperzija brzina. Wake et al. (2012) pokazuju da disperzija brzina koreliše sa $g - r$ bojom bolje od zvezdane mase (M_*), Sersikovog indeksa (n) i površinske gustine ($\Sigma \sim M_*/r_e$), sugerišući da je istorija formiranja zvezda (parametrizovana bojom), direktno zavisna ili čak vođena centralnom supermasivnom crnom rupom. Zbog ove svoje osobine, disperzija brzina će biti korišćena kao dodatni parametar u daljoj analizi. Postoje još dve fundamentalne osobine galaksija (pored ukupne mase), koje se mogu izraziti koristeći parametre analizirane u ovoj tezi i to su:

- i) specifični ugaoni moment galaksije $j_* = hV_r/M_*$, gde je V_r maksimalna rotaciona

brzina, a M_* masa zvezdane komponente i

- ii) njena ukupna energija $E = 3/2M_{\text{tot}}\sigma^2$, gde je σ disperzija brzina galaksije, a M_{tot} njena ukupna masa.

Specifični ugaoni moment zahteva uvođenje maksimalne rotacione brzine u analizu i ona je dostupna iz ALFALFA pregleda. Zvezdana masa biće izvedena iz boje $g - r$ (Bell et al., 2003). Dinamička masa će biti izvedena iz disperzije brzina, Sersikovog indeksa i efektivnog radijusa i koristiće se kao ukupna masa galaksije. Još dve nove fundamentalne osobine galaksija dodate su analiziranom prostoru parametara: starost i metaličnost galaksija, odnosno njihovi indikatori Likovi indeksi H_β i $\langle \text{Fe}' \rangle$. Nešto veći skup parametara, nakon testiranja, sveden je na konačni skup od deset parametara i to su: Petrosijanovi radijusi koji obuhvataju 50% i 90% ukupnog fluksa galaksije (R_{50} i R_{90}), luminoznost u g filteru (L_g), masa zvezdane i gasne komponente (M_k i M_{HI}), boja ($NUV - r$), disperzija brzina (σ), maksimalna rotaciona brzina galaksija (V_r), Likov indeks H_β kao indikator starosti i dinamička masa (M_{dyn}). Od ovih parametara, u tezi su izračunate disperzije brzina, Likovi indeksi i dinamička masa (iz Sersikovog modela). Ostali parametri preuzeti su iz baza podataka: Petrosijanovi radijusi i magnituda u r filteru, preuzeti su iz SDSS DR7 baze, masa gasne komponente i maksimalna rotaciona brzina iz $\alpha.40$ kataloga, a NUV magnituda iz GALEX baze podataka. Masa zvezdane komponente, izračunata je pomoću boje $g - r$, preuzete iz SDSS baze podataka.

1.10 Struktura teze

Cilj ove teze jeste pronalaženje minimalnog broja dimenzija višedimenzionalnog prostora osobina galaksija, koji je dovoljan da ih u potpunosti opiše. U tu svrhu primenjena je statistička analiza nad skupom detaljno ispitanih parametara koji oslikavaju fundamentalne osobine galaksija, na morfološki reprezentativnom i statistički značajnom uzorku od 2180 galaksija. Uzorak je zasnovan na Alfalfa HI pregledu neba, koji je kombinovan

sa optičkom spektroskopijom iz SDSS baze podataka i fotometrijom od ultraljubičastog (GALEX baza podataka), preko optičkog (SDSS baza podataka) do bliskog infracrvenog dela spektra (2MASS baza podataka), kako bi se dobio finalni set analiziranih podataka, koji dalje u tezi nazivamo α -uzorak.

U drugom poglavlju teze definisan je uzorak galaksija korišćen u tezi i ispitana je nje-gova morfološka reprezentativnost. U trećem poglavlju izračunata je detaljna kinematika zvezda, uključujući više momente raspodele brzina na koje su primenjeni su statistički testovi za različite grupe morfoloških tipova galaksija. Ovo je do sada najveći uzo-rak galaksija za koji je izmerena detaljna kinematika zvezda uključujući više momente raspodele brzina.

U četvrtom poglavlju izmereni su indeksi jačine pojedinih apsorpcionih linija u spe-ktru, koji mogu poslužiti kao indikatori starosti i metaličnosti. Nezavisno od toga, urađeno je modelovanje celog spektra sa ciljem određivanja starosti i metaličnosti. Poređe-njem spektralnih indeksa sa modelovanom starošću i metaličnošću, odabrana su dva indeksa, kao najbolja indikatora starosti i metaličnosti.

U petom poglavlju detaljno je opisan postupak modelovanja površinskog sjaja galak-sija iz optičke fotometrije (SDSS DR8) u r filteru, sa ciljem određivanja Sersikovog in-deksa i efektivnog radijusa Sersikovog modela, pomoću kojih će biti izračunata dinamička masa. Za izračunavanje dinamičke mase, potreban je još jedan parametar, disperzija brz-ina, izračunata u trećem poglavlju. Dinamička masa je fundamentalna osobina galaksija, što je čini značajnim parametrom u statističkoj analizi sprovedenoj u šestom poglavlju.

U šestom poglavlju urađena je korelaciona analiza ispitujući linearne relacije među skupom parametara koji opisuju "prostor galaksija". Konačni skup analiziranih param-etara čine: Petrosijanovi radijusi koji obuhvataju 50% i 90% ukupnog fluksa galaksije (R_{50} i R_{90}), luminoznost u g filteru (L_g), masa zvezdane i gasne komponente (M_k i M_{HI}), boja ($NUV - r$), disperzija brzina (σ), maksimalna rotaciona brzina galaksija (V_r), Likov indeks H_β kao indikator starosti i dinamička masa (M_{dyn}). Nasuprot prethod-

nim radovima, koji su se zasnivali na fotometrijskim podacima, krajnjem analiziranom skupu galaktičkih osobina, dodata su dva "spektroskopska" podatka: disperzija brzina zvezda u galaksiji i starost galaksija. Zatim je primenjena PCA metoda nad ovim skupom parametara, sa ciljem pronalaženja najmanjeg broja dimenzija (osnovnih komponenata), dovoljnih da opišu višedimenzionalni prostor osobina galaksija.

Konačno, u poslednjem delu teze, dat je rezime disertacije, zaključci istraživanja i predlozi budućih istraživanja, praćeni spiskom korišćenih referenci. U Dodatnom materijalu ove teze detaljno je opisan postupak dobijanja α -uzorka, osnovni podaci o galaksijama kao i rezultati svih urađenih testova, modela i merenja parametara.

Poglavlje 2

α -uzorak galaksija

2.1 ALFALFA pregled

ALFALFA pregled je radio-pregled naslepo na 21 cm liniji neutralnog vodonika. To je pregled druge generacije i karakteriše ga veća osetljivost i ugaona rezolucija u odnosu na preglede prve generacije, kakav je bio HIPASS. Aresibo je najosetljiviji radio-teleskop na svetu u tzv. L-opsegu, što je zapravo opseg frekvencija na kojima instrument radi (1225-1525 MHz). Frekvencija linije neutralnog vodonika HI je 1420.4 MHz, i odgovara joj talasna dužina od 21 cm. *Arecibo L-band Feed Array* (skraćeno, ALFA) je instrument napravljen u Australiji, dizajniran tako da detektuje istovremeno radio signal sa sedam tačaka na nebu, praveći sliku od 7 piksela.

ALFA instrumentom je pregledano 7000 deg² i detektovano više od 30 000 izvora do crvenog pomaka $z \sim 0.06$. Ovaj pregled je posebno koristan u sinergiji sa pregledima na drugim talasnim dužinama kao što su: SDSS, 2MASS, WISE ¹, GALEX itd.

Na ovom mestu pomenuću najznačajnije rezultate koje je iznedrio ALFALFA pregled:

1) Merenjem tzv. funkcije širine brzina (engl. velocity width function) HI linije (w)

¹Wide-field Infrared Survey Explorer, skraćeno WISE (<http://wise.ssl.berkeley.edu/index.html>) je pregled neba u srednjem infracrvenom delu spektra (3.5 - 23 μm)

na uzorku od preko 10 000 galaksija, pokazalo se da su galaksije širina HI linije $w < 20$ km/s čak 100 puta manje zastupljene u odnosu na raspodelu haloa malih masa koju predviđa Λ CDM model.

2) Halo malih masa sadrže i za red veličine manje bariona² nego što to predviđa Λ CDM model, čak i kada se uzme u obzir atomska masa, koja u slučaju patuljastih galaksija dominira ukupnom barionskom masom. Da bi se Λ CDM model "pomirio" sa ovim rezultatima, potrebno je postojanje veoma efikasnog mehanizma koji galaksije osiromašuje barionima, i to takvog koji bi mogao da izbaciti iz galaksije 100 puta više gasa u odnosu na zvezde koje "ostavlja".

3) Grupisanje (engl. clustering) galaksija ne pokazuje nikakvu varijaciju sa HI masom ($10^{7.5} < M_{\text{HI}} < 10^{11} M_{\odot}$), dok u slučaju Λ CDM haloa postoji jasna tendencija većeg grupisanja masivnijih haloa. Zaključak bi mogao biti: galaktička HI masa veoma malo zavisi od mase haloa galaksija domaćina.

Ovo poglavlje je koncipirano na sledeći način: u potpoglavlju 2.1 opisan je ALFALFA pregled neba; u potpoglavlju 2.2 objašnjeni su postupci kojima je dobijen konačan uzorak od 2180 galaksija, korišćen u ovoj tezi; u potpoglavlju 2.3 prikazana je morfološka raspodela galaksija i pokazano da galaksije iz konačnog uzorka morfološki reprezentativne u lokalnom Univerzumu.

2.2 $\alpha.40$ katalog

U ovoj tezi i radu Vudragović et al. (2016), korišćen je deo kataloga $\alpha.40$ (Haynes et al., 2011), koji sadrži oko 40% pregleda, ukršten sa SDSS DR7 spektroskopskim katalogom

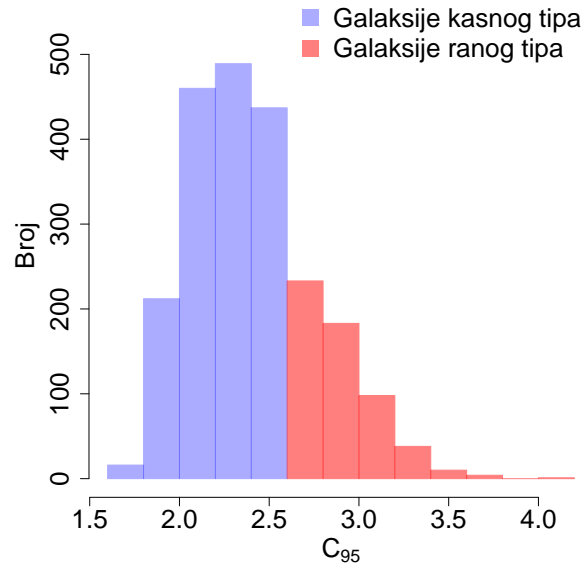

²Luminoznu materiju, koja se može detektovati putem elektromagnetnog zračenja, čine protoni i neutroni (jednom rečju barioni) i elektroni i zajedno čine $\sim 5\%$ ukupne materiju u Univerzumu. Preostalih $\sim 95\%$ čine tamna materija ($\sim 25\%$) i tamna energija ($\sim 70\%$). Tamna materija, iako ne emituje svetlost raspolaže masom, te se može detektovati putem gravitacionog dejstva, koje ima na luminoznu materiju. Pretpostavlja se da je tamna energija odgovorna za ubrzavanje širenja Univerzuma.

(Abazajian et al., 2009). Izvorno, ovaj katalog broji 9966 galaksija. Zahtevanjem čiste fotometrije iz SDSS baze podataka (npr. birajući samo galaksije dovoljno udaljene od ivice slike) i izdvajanjem samo onih objekata koji su od strane SDSS-a klasifikovani kao galaksije, uzorak se smanjuje na 6732 galaksije. Dodavanjem ultraljubičaste fotometrije, koristeći šesto izdanje (GR6) podataka iz baze GALEX, uzorak se dalje smanjuje na 4568 galaksija. Najzad, pozicionim ukrštanjem sa fotometrijskim katalogom 2MASS XSC dostupnim u 2MASS bazi podataka, uz sugerisana ograničenja na fotometriju i u okviru $3''^3$, dobija se konačan uzorak od 2180 galaksija, odnosno α -uzorak. Ovaj uzorak raspolaže optičkom i radio-spektroskopijom i fotometrijom od ultraljubičastog do bliskog infracrvenog dela spektra. Detalji o pretraživanju baza podataka prilikom sastavljanja konačnog uzorka, nalaze se u Dodatku A. Osnovni podaci o galaksijama iz α -uzorka dati su u tabeli B.1 (Dodatak B) i to su: identifikacioni broj u α .40 katalogu, ekvatorijalne koordinate (J2000), identifikacioni brojevi u svim katalogima sa kojim je ukršten (SDSS, GALEX, 2MASS), crveni pomak, odnos signala prema šumu i informacija o morfološkom tipu galaksije. Pomoću ovih podataka, svaka galaksija iz α -uzorka se može identifikovati, bilo putem identifikacionih brojeva, bilo poziciono, putem prostornih koordinata.

2.3 Morfološka raspodela galaksija

Morfološka raspodela galaksija zasnovana je na tzv. indeksu koncentracije (engl. concentration index), kao odnosu radijusa koji sadrže, redom, 90% i 50% Petrosijanovog fluksa, tj. $C_{95} = R_{90}/R_{50}$. Raspodela galaksija prema indeksu koncentracije nam otkriva da ima približno 1/3 galaksija ranog tipa (slika 2.1). Ova podela izvršena je pomoću granične vrednosti $C_{95} \geq 2.6$, koja se pokazala uspešnim diskriminatorom između dva glavna tipa galaksija (ranog i kasnog tipa) u radu Strateva et al. (2001). α -uzorak raspolaže sa 26% galaksija ranog tipa (eliptične i sočivaste), naspram 74% ostalih tipova galaksija (spiral-

³Radijus od $3''$ jednak je prečniku optičkog vlakna unutar kojeg je snimljen spektar.

Slika 2.1: Histogram morfološkog tipa galaksija iz α -uzorka korišćenog u ovoj tezi, zasnovan na graničnoj vrednosti parametra koncentracije $C_{95} \geq 2.6$ za rane i $C_{95} < 2.6$ za kasne galaksije.

nih i nepravilnih). Odnos 2:3 reflektuje zastupljenost galaksija dva glavna morfološka tipa u lokalnom Univerzumu (Shimasaku et al., 2001).

Sa druge strane, Huertas-Company et al. (2011) izvršili su automatsku klasifikaciju svih galaksija iz SDSS DR7 kataloga, na nižim crvenim pomacima. Oni nude kontinuiranu verovatnoću pripadanja galaksije jednoj od dve glavne grupe ili tipa (rane ili kasne galaksije), ali i dve podgrupe u okviru svake od ovih grupa: eliptične (E) i sočivaste (S0), kao podgrupe ranog tipa i spiralne Sab i Scd, kao podgrupe kasnog tipa galaksija. Svaka galaksija ima odgovarajuću verovatnoću pripadanja određenom tipu, ali u zbiru sve ove "parcijalne" verovatnoće jednake su jedinici. Na primer, za galaksiju bi parcijalne verovatnoće mogle iznositi: $p_E + p_{S0} + p_{Sab} + p_{Scd} = 0.7 + 0.2 + 0.05 + 0.05 = 1$, odnosno verovatnoća je normirana na jedinicu. Granična vrednost pripadanja galaksije odgovarajućoj podgrupi galaksija iznosi 0.5 i dobijena je poređenjem sa *Galaxy Zoo*⁴ vizuelnom klasifikacijom i još nekoliko metoda (videti Huertas-Company et al. (2011) za više detalja). U prethodnom primeru galaksija se može klasifikovati kao eliptična, pošto

⁴Galaxy Zoo je projekat koji ima za cilj vizuelnu morfološku klasifikaciju nekoliko miliona galaksija iz SDSS baze podataka, uključujući volontere širom sveta: <https://www.galaxyzoo.org>

je $p_E = 0.7$ ($p_E \geq 0.5$). Osnovne podgrupe su eliptične (E), sočivaste (S0), spiralne galaksije tipa a ili b (Sab) i spiralne galaksije tipa c ili d (Scd). Ove podgrupe formiraju glavne grupe: galaksije ranog ($p_E + p_{S0} \equiv p_{ES0} \geq 0.5$) i galaksije kasnog tipa ($p_{Sab} + p_{Scd} \equiv p_S > 0.5$). Prema ovoj klasifikaciji, uzorak galaksija korišćen u ovoj tezi sastoji se 13% od ranih (E + S0) i 87% od kasnih (Sab + Scd) galaksija.

Poglavlje 3

Kinematički profili bliskih galaksija

Kinematika galaksija odražava kretanje zvezda i gasa u zajedničkom gravitacionom potencijalu koji je dominantno određen raspodelom tamne materije. Posmatrani spektar galaksije je zbirni spektar pojedinačnih zvezda koje se kreću brzinama iz neke zajedničke raspodele brzina projektovanih na pravac posmatranja (engl. line-of-sight).

Raspodelu brzina zvezda odgovornu za konačan izgled linija u spektru galaksije zvaćemo raspodela brzina duž pravca posmatranja (engl. line-of-sight velocity distribution, skraćeno LOSVD). Pored uređenog rotacionog kretanja zvezda vezanih za disk, može se javiti i neuređeno kretanje zvezda vezanih za centralni oval (disperzija brzina). Kada je efekat neuređenosti mali, kao kod spiralnih galaksija (galaksija kasnog tipa, engl. late-type galaxies) gde je dominantna rotacija zvezda, disperzija brzina je mala i na granici instrumentalne rezolucije i profili apsorpcionih linija, koji reflektuju raspodelu projektovanih brzina zvezda se mogu uspešno opisati pomoću Gausove funkcije. Međutim, kod eliptičnih i sočivastih galaksija, rečju kod galaksija ranog tipa (engl. early-type galaxies), ali i spiralnih galaksija sa klasičnim centralnim ovalom, posmatrajući centralne delove galaksija gde je disperzija najveća, raspodela brzina zvezda odstupa od čistog Gausijana (Samurović & Danziger, 2005; Samurović, 2007) i zahteva uvođenje dodatnih parametara za opis profila apsorpcionih linija. Razmatrajući modele spiralnih

i eliptičnih galaksija, van der Marel & Franx (1993) pokazuju da aproksimacija Gausijanom unosi greške od čak 10% u radijalnu brzinu i disperziju brzina, čak i u slučaju manjih odstupanja od Gausijana. Oni predlažu razlaganje posmatrane raspodele brzina zvezda na ortogonalne funkcije, odnosno u Gaus-Hermitov niz. Na ovaj način, pored Gausijana, uvode se dva nova parametra koji opisuju asimetrična i simetrična odstupanja od čistog Gausijana (anizotropije brzina). U pionirskim radovima, koji razmatraju anizotropije u profilima brzina (Gerhard, 1993), kinematika zvezda bila je zasnovana na *jednoj zvezdi*, koja je bila posmatrana sa istom konfiguracijom instrumenata (spektrografa) kao i galaksija, dok su danas na raspolaganju biblioteke zvezdanih spektara koje broje ~ 1000 zvezda. Naime, spektar galaksije je integralni spektar zvezda različitih osobina i poseban problem pri merenju kinematike jeste odabir odgovarajuće zvezdane biblioteke.

U ovom poglavlju biće razmotreno odstupanje raspodele brzina od Gausove funkcije i pokazano koliki je efekat zanemarivanja negausovske komponente brzine. Imajući u vidu da disperzija brzina centralnog ovala figuriše u mnogim empirijskim relacijama, koje ćemo nazvati sigma-stepene relacije, s obzirom na to da disperzija u njima figuriše sa stepenom, pokazaćemo koliko se potcenjivanje/precenjivanje disperzije brzina odražava na veličine koje korelišu sa disperzijom. Pomenuću najpoznatije relacije: $M_{\text{BH}}-\sigma$ relacija (veza između mase crne rupe i centralne disperzije) i virijalna masa - disperzija brzina.

Kako su negausovski efekti mali, potrebni su spektri visoke rezolucije, odnosno visokog odnosa signala prema šumu (engl. signal-to-noise ratio, skraćeno SNR) kako bi ovakva korekcija postala značajna. U ovom poglavlju biće pokazano da kod $\text{SNR} \approx 50$, relativne greške Gaus-Hermitovih koeficijenata padaju ispod 50%. Značajno je pomenuti da je negausovska korekcija često nepravedno zanemarena, čak i u SDSS-u, koji predstavlja trenutno najveću bazu optičkih spektara. Ovo je neobično, s obzirom na to da su u pitanju spektri centralnih delova galaksija, gde je negausovski efekat najizraženiji.

Ovo poglavlje je koncipirano na sledeći način: u potpoglavlju 3.1 dat je osnovni kon-

cept Gaus-Hermitovih polinoma i diskutuje se opravdanost uvođenja dodatnih parametara; u potpoglavlju 3.2 opisana je biblioteka zvezdanih spektara korišćena u radu i diskutuje se problem nepodudarnosti zvezdanih spektara; u potpoglavlju 3.3 diskutuje se opravdanost negausovske korekcije i njene implikacije; u potpoglavlju 3.4 predstavljeni su rezultati statističkih testova nad višim momentom raspodele brzina (h_4).

3.1 Kinematika zvezda

Spektar galaksije može se predstaviti zbirom zvezdanih spektara, kao integralni zvezdani spektar sačinjen od zvezda različitih tipova koje se kreću različitim brzinama, projektovanih na pravac posmatranja. Njihova raspodela brzina merena iz profila apsorpcionih linija ima oblik gausovske raspodele, ali u slučaju da se jave odstupanja od ovako proste funkcije, možemo ih kvantifikovati kroz dodatne članove tzv. Gaus-Hermitovog niza. Gausova funkcija opisuje se pomoću: intenziteta linije (γ), srednje radijalne brzine ili Doplerovog pomeranja linije (V) i disperzije brzina (σ). Dakle, profil linije može se predstaviti sa:

$$L(v) = \gamma\alpha(w)/\sigma, \quad w = (v - V)/\sigma \quad (3.1.1)$$

gde je $\alpha(w)$ standardni Gausijan:

$$\alpha(w) = \frac{1}{\sqrt{2\pi}} e^{-1/2w^2}. \quad (3.1.2)$$

Merenje odstupanja profila linije od čistog Gausijana jedno vreme se zasnivalo na dekompoziciji profila na dva Gausijana. Međutim, dobijeni parametri snažno korelišu i osim u slučaju postojanja dve različite kinematičke komponente, teško ih je interpretirati. Zato su van der Marel & Franx (1993) predložili računanje viših momenata profila linije. Posmatrani profil linije može se predstaviti sumom ortogonalnih funkcija iz Gaus-Hermitovog niza. Ovaj pristup zasnovan je na činjenici da je Gausijan dobra aproksimacija realnih linija i uvodi dva dodatna parametra koja opisuju asimetrična

(h_3) i simetrična (h_4) odstupanja. Ortogonalne funkcije drastično smanjuju potencijalne korelacije među parametrima. Profil linije dat je sa:

$$L(v) = [\gamma\alpha(w)/\sigma] \left\{ 1 + \sum_{j=3}^N h_j H_j(w) \right\}, \quad w = (v - V)/\sigma. \quad (3.1.3)$$

gde su h_j slobodni parametri (Gaus-Hermitovi koeficijenti, u daljem tekstu), a $H_j(w)$ Hermitovi polinomi. Izrazi za treći i četvrti polinom, koji su korišćeni u tezi, dati su sa:

$$H_3(w) = \frac{w(w^2 - 3)}{\sqrt{3}}, \quad H_4(w) = \frac{w^2(4w^2 - 12) + 3}{\sqrt{24}}. \quad (3.1.4)$$

Postoje i viši momenti funkcije, odnosno Gaus-Hermitovi koeficijenti h_5 , h_6 itd.

Kako bi se kvantifikovala potreba za uvođenjem negausijanskih parametra, van der Marel & Franx (1993) definišu devijaciju D Gaus-Hermitove funkcije u odnosu na Gausovu funkciju, preko Gaus-Hermitovih koeficijenata:

$$D = \sqrt{\sum_{j=3}^{\infty} h_j^2}. \quad (3.1.5)$$

Za rekonstrukciju kinematičkog profila galaksija, korišćen je javno dostupan program Penalized Pixel-Fitting (skraćeno pPXF), opisan u radu Cappellari & Emsellem (2004)¹. Zasnovan je na nelinearnoj metodi najmanjih kvadrata koja čini jezgro programa². Ova metoda prihvata rezidualne modele i ulaznih podataka kao:

$$r_i = \frac{y_i - f(x_i, p)}{\sigma_i}, \quad i \in (1..N) \quad (3.1.6)$$

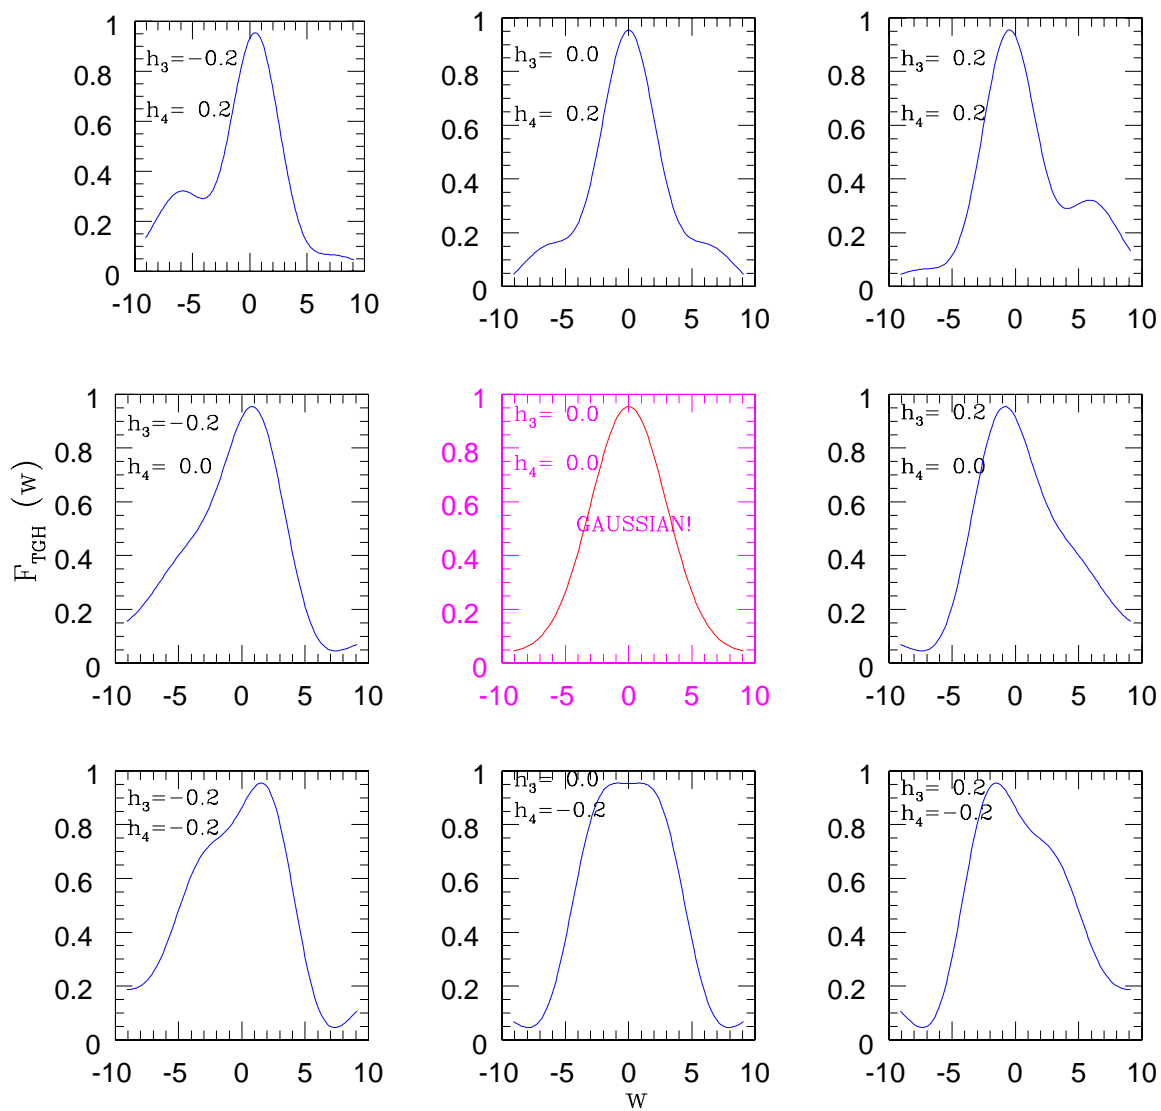

gde su r_i reziduali, y_i merenja opservable, N broj merenja, $f(x_i, p)$ model sa parametrima p , a σ_i greške merenja, i minimizira sumu kvadrata reziduala (tzv. χ^2 -statistika³):

$$\chi^2 = \sum_i^N r_i^2. \quad (3.1.7)$$

¹<http://www.astro.physics.ox.ac.uk/~mxc/software/#ppxf>

²<https://www.physics.wisc.edu/~craigm/idl/fitting.html>

³U slučaju gausovske statistike, χ^2 -minimizacija ekvivalentna je metodi najveće verodostojnosti (engl. maximum likelihood).

Slika 3.1: Viši momenti Gaus-Hermitovog niza h_3 i h_4 , koji opisuju asimetrična i simetrična odstupanja od Gausijana, redom. Centralna slika odgovara čistom Gausijanu ($h_3 = h_4 = 0$), poređenja radi. Izvor: Samurović (2007).

pPXF prihvata (formalno) neograničen broj zvezdanih spektara, množi ih težinama i konvoluira u parametarskom prostoru sa Gaus-Hermitovom funkcijom. Ovako se formira model $f(x_i, p)$ u jednačini 3.1.6 i rešava *simultano* za nepoznate parametre (p): amplitude zvezdanih spektara (γ) i Gaus-Hermitove koeficijente (V, σ, h_i). Postavlja se pitanje koliko viših momenata (h_i) je opravdano koristiti u modelu. Cappellari & Emsellem (2004) su implementirali formulu 3.1.5 kao kontrolni parametar. Parametar D^2 doveden je u vezu sa rezidualima fita galaktičkih spektara, kako bi potreba za uvođenjem dodatnih parametara prilikom fitovanja postala merljiva, pošto povećanje broja parametara formalno dovodi do poboljšanja fita, jer važi:

$$\chi_p^2 = \chi^2(1 + \lambda^2 D^2), \quad (3.1.8)$$

gde je χ_p^2 zapravo χ^2 fita koji uključuje više momente (jednačina 3.1.5), a χ^2 dobijen je fitovanjem Gausovom funkcijom. Kontrolni parametar, koji treba unapred odrediti je tzv. parametar pristrasnosti (λ ; engl. bias). Vrednost χ^2 fita dobija se fitovanjem Gausovom funkcijom, dok je χ_p^2 suma reziduala dobijena uvođenjem Gaus-Hermitovih polinoma. Kada je fit dobar $\chi^2 \sim N$. Za dati λ parametar, devijacija D od Gausijana mora da smanji χ^2 za više od $\Delta\chi^2 \sim N\lambda^2 D^2$, kako bi Gaus-Hermitovi koeficijenti bili prihvaćeni kao realno poboljšanje fita. U ovoj tezi, kao što je već napomenuto, korišćeni su momenti h_3 i h_4 , odnosno analitički izraz za LOSVD:

$$L(w) = \alpha(w)[1 + h_3 H_3(w) + h_4 H_4(w)] \quad (3.1.9)$$

i ilustracije radi na slici 3.1, prikazana je ova funkcija za različite vrednosti parametara h_3 i h_4 . Ova funkcija je otežinjena amplitudama zvezdanih spektara, koji odgovaraju parametru jačine linje γ u jednačini 3.1.3.

Greške momenata Gaus-Hermitovih polinoma umnogome zavise od SNR-a. SNR varira od 5 do 80, sa medijanom SNR = 35. Tek kod spektara sa SNR > 50, relativne greške parametara h_3 i h_4 padaju ispod 50%.

Pretpostavimo da spektar galaksije u potpunosti korespondira spektru neke zvezde iz raspoložive biblioteke zvezdanih spektara. Da li je i u kom slučaju potrebno uvesti dodatne Gaus-Hermitove koeficijente? U stvarnosti, naravno, tek brižljivo odabran zbir spektara zvezda može opisati galaksiju i na to ćemo se vratiti u sledećem potpoglavlju. Zasad, razmotrimo idealan slučaj galaksije čiji spektar odgovara jednoj zvezdi sa nenultom disperzijom. Da bismo ustanovili kako rezultati fitovanja zavise od SNR-a, spektar proizvoljne zvezde proširićemo Gaus-Hermitovim polinomima, gde su nam, dakle veličine V , σ , h_3 i h_4 unapred poznate (zadajemo ih) i dodavanjem šuma pokušaćemo da rekonstruišemo inicijalne vrednosti. Koraci su prikazani sledećim formulama iz pPXF programa:

$$\text{LOSVD} = \text{GAUSS} * (1 + h_3 * H_3 + h_4 * H_4) \quad (3.1.10)$$

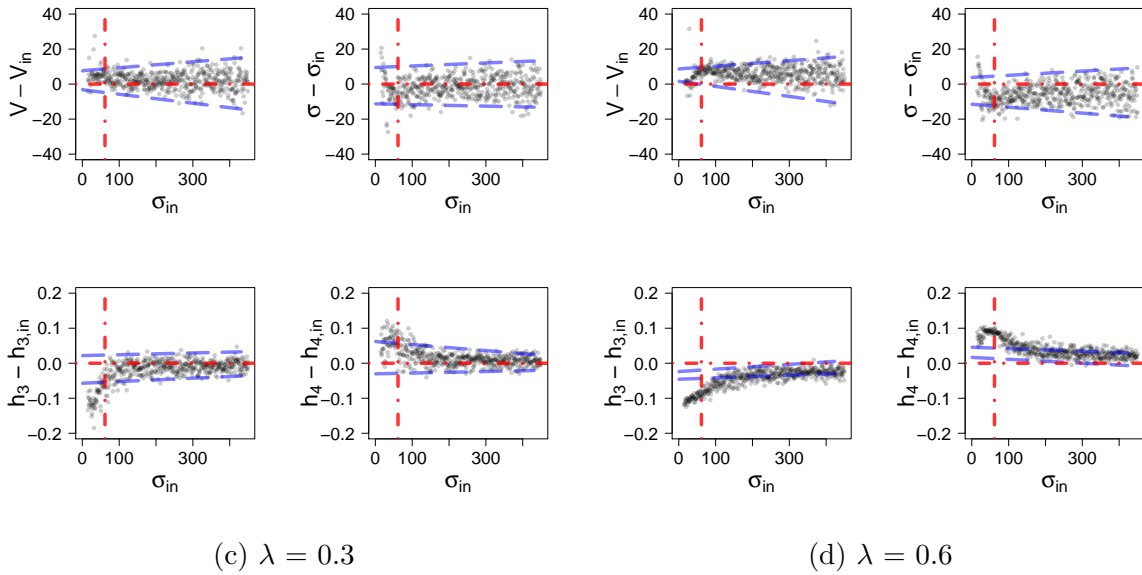

$$\text{GALAXY} = \text{STAR} \odot \text{LOSVD} + \text{GALAXY}/\text{SNR} * \text{randomn}(s, n) \quad (3.1.11)$$

U prvom koraku se generiše profil linije, odnosno funkcija širenja, tj. Gaus-Hermitov polinom zadatih Gaus-Hermitovih koeficijenata (h_3 i h_4). U drugom koraku se spektar zvezde konvoluirsa sa ovom funkcijom, a zatim se ovom proširenom zvezdanom spektru dodaje "šum" okarakterisan unapred zadatim SNR-om, kome se dodaje normalan (Gausov) šum funkcijom *randomn*. Funkcija *randomn* generiše niz pseudoslučajnih brojeva iz Gausove raspodele. Zapravo, količnik GALAXY/SNR degradira spektar galaksije na željeni SNR. Varirajući SNR od 5 do 80, može se odrediti za svaki SNR iz opsega najveći λ parametar za koji se još h_3 i h_4 mogu rekonstruisati. Na slici 3.2, dat je primer variranja λ parametra od 0.1 do 0.6, gde se zapravo treba zaustaviti na $\lambda = 0.3$, pošto je ovo najveća vrednost za koju Gaus-Hermitovi koeficijenti ostaju unutar šuma i ne pokazuju nikakvu asimetriju oko linije $h_{3,in} - h_3 = 0$; dok se na poslednjoj slici (d) vidi jasna asimetrija oko horizontalne crta-tačka linije.⁴ Indeks *in* odnosi se na inicijalnu vrednost h_3 parametra, a h_3 se dobija fitovanjem "lažnog" spektra galaksije Gaus-Hermitovom funkcijom, za ra-

⁴Horizontalna crta-tačka linija označava liniju jednakih simuliranih i zadatih vrednosti Gaus-Hermitovih koeficijenata. Upravna linija jednaka je instrumentalnoj rezoluciji SDSS spektara (70 km/s).

zličite, unapred zadate λ parametre. Upravna crta-tačka linija označava instrumentalnu rezoluciju SDSS spektara (70 km/s).

Za svaki SNR = (5, 80) sa korakom od 5, na ovaj način je određen λ parametar. Iz ovih simulacija takođe je moguće dobiti greške fitovanih parametara (V , σ , h_3 , h_4) iz rasipanja oko horizontalne (crvene) crta-tačka linije⁹. Prvo su odbačene sve tačke koje padaju izvan oblasti određene sa 1σ , gde je σ standardna devijacija odstupanja tačaka od horizontalne linije. Zatim su locirane najudaljenije preostale tačke, one koje još ulaze u 1σ , i sa obe strane $y = 0$ linije (i odozdo i odozgo) ove tačke su fitovane linearnom funkcijom. Ova funkcija za svaku disperziju daje raspon greške ka gornjem i donjem delu grafika, podeljenog horizontalom. Izborom veće greške od ove dve, za svaku disperziju, dobijamo veoma konzervativne greške, koje ćemo koristiti dalje u radu.

Slika 3.2: Simulacija variranja λ parametra iz pPXF programa, odnosno jednačine 3.1.8 za $\text{SNR} = 35$. Redom su prikazani rezultati za $\lambda = 0.1, 0.2, 0.3, 0.6$. Za svaku od ovih vrednosti λ parametra, data su odstupanja parametara V, σ, h_3 i h_4 (simulirane vrednosti) u odnosu na njihove inicijalno zadate vrednosti. Upravna crta-tačka linija je instrumentalna rezolucija SDSS spektara i iznosi 70 km/s. Isprekidane linije su asimptote, čija širina daje greške pomenutih parametara za datu vrednost disperzije brzina, označene na x-osi.

3.2 Zvezdane biblioteke

Veliki nerešen problem određivanja osobina galaksije (između ostalih i disperzije brzina) iz zvezdanih spektara jeste nalaženje integralnog zvezdanog spektra koji u potpunosti korespondira sa spektrom galaksije u određenom trenutku njene evolucije. Ovom pitanju se može pristupiti korišćenjem velike baze empirijskih zvezdanih spektara, koji imaju dovoljnu pokrivenost relevantnih parametara (efektivna temperatura, površinska gravitacija i metaličnost zvezda). Pa ipak, pošto se "prave" (empirijske) zvezde nalaze u blizini Sunca, one ne mogu sasvim opisati galaksije različitih tipova i hemijskog sastava. Zato sve više postaje prihvaćen drugačiji pristup – korišćenje sintetičkih spektara širokog opsega starosti i metaličnosti (zvezdane populacije), kod kojih se čak može dodati još jedan parametar, obogaćenost α -elementima.⁵ Pokazuje se da je upravo ovaj parametar ključan za modelovanje eliptičnih galaksija, kao i centralnih ovala spiralnih galaksija.

Poznate i javno dostupne biblioteke posmatranih zvezdanih spektara uključuju: Elodie (Prugniel et al., 2007)⁶, Miles (Vazdekis et al., 2010)⁷, Indo-US (Valdes et al., 2004)⁸, Stelib (Le Borgne et al., 2003)⁹, Lick (Gorgas et al., 1993; Worthey et al., 1994)¹⁰ itd. Na slici 3.3 prikazan je deo zvezda (patuljaka i džinova) iz ovih biblioteka poređenja radi. Najbolju pokrivenost u prostoru zvezdanih parametara pruža Miles biblioteka. Metaličnost bliska Sunčevoj je dobro pokrivena u svim bibliotekama ($[Fe/H] = 0$), ali kod niže metaličnosti izdvaja se ponovo Miles biblioteka, kako kod patuljastih, tako i kod džinovskih zvezda.

Pošto posmatranih zvezda u svakoj od biblioteka ima veliki broj, a galaksija u našem α -uzorku ima preko 2000, empirijske biblioteke su testirane na manjem uzorku galaksija,

⁵ α -elementi su O, Mg, Si, S, Ca i Ti. Obogaćenje α -elementima (engl. α -enhancement) u odnosu na gvožđe nastaje kroz eksplozije supernovih tipa IIa.

¹⁰<http://astro.wsu.edu/worthey/html/sdr.html>

Slika 3.3: Zavisnost efektivne temperature (θ) od metaličnosti ($[\text{Fe}/\text{H}]$) iz javno dostupne biblioteke zvezdanih spektara prikazane poređenja radi. Patuljaste (gornji grafik) i džinovske zvezde (donji grafik) razdvojene su uslovom da je površinska gravitacija $\log g = 3$. Izvor: Vazdekis et al. (2010).

Slika 3.4: Galaksija NGC 2410 prikazana u SDSS bazi: crveni kvadrat je veličine 3 lučne sekunde i obuhvata region odakle potiče spektar. U pitanju je galaksija sa aktivnim jezgrom na malom crvenom pomaku ($z \sim 0.016$).

takođe reprezentativnom u pogledu morfologije. Manji uzorak galaksija formiran je iz dva izvora: iz rada Ho (2007) kojim dominiraju spiralne galaksije i iz Bliskog optičkog kataloga galaksija (engl. Nearby Optical Galaxy Catalog; Giuricin et al. (2000)) birajući samo galaksije ranog tipa. Uzorak broji 657 galaksija i potpuno je nezavisan od α -uzorka. Sve biblioteke empirijskih zvezdanih spektara imaju nedostajuće vrednosti fluksa u spektrima. Kako se ne bi unosile dodatne neodređenosti interpolacijom većih regiona koji nedostaju, odabrane su samo one zvezde koje nemaju "prazninu" veću od 100 \AA i više od jednog "lošeg" piksela na krajevima spektra¹¹ (pPXF program ne uzima u obzir nekoliko piksela na krajevima spektra). Ostali regioni sa nedostajućim vrednostima fluksa interpolirani su kubnim polinomom i tako popunjeni. U drugoj koloni tabele 3.1 dat je početni broj zvezda u bibliotekama, a u sledećoj koloni konačni broj, odnosno broj zvezda gde su falični regionu u spektrima dovoljno mali da se mogu interpolirati.

Na primeru galaksije NGC 2410 (slika 3.4), najbolje se mogu uporediti rezultati merenja kinematike koristeći zvezdane spektre iz različitih biblioteka (slike 3.5 i 3.6). Različitim bojama prikazana je pokrivenost SDSS opsegom zvezdanih spektara iz bi-

¹¹Tzv. loši pikseli su oni pikseli u kojima fluks nedostaje pa im je pridodata vrednost nula.

blioteka (levo) i rezultati pPXF koda u ovim regionima (desno). Galaksija NGC 2410 ima aktivno jezgro i pored uspešnosti fita, odabrana je da prikaže značaj maskiranja emisionih linija. α -uzorkom dominiraju galaksije sa visokom stopom formiranja zvezda (engl. starforming galaxies) i samim tim obiluju emisionim linijama.

Za svaku od biblioteka (tabela 3.1) određen je λ parametar za dati opseg SNR-a i izmerena kinematika uključujući više momente funkcije raspodele brzina. Izmerena disperzija brzina (gausovska), dobijena korišćenjem različitih empirijskih biblioteka međusobno je upoređena, kako bi se ustanovilo postoji li međusobno sistematsko odstupanje merenih vrednosti. Takođe, izmerene disperzije brzina upoređene su i sa rezultatima dostupnim u SDSS bazi podataka (slika 3.7). Na slici 3.7 dato je poređenje sledećih empirijskih zvezdanih biblioteka: SDSS, Stelib, Indo-US, Elodie i Miles. Puna linija odgovara funkciji $y = x$ i svako sistematsko odstupanje od ove linije predstavlja sistematiku, koja govori o međusobnom nepodudaranju zvezdanih spektara pomenutih biblioteka. Razlog ovog nepodudaranja leži ili u različitoj zastupljenosti odgovarajućih tipova zvezda ili u nedovoljnom broju zvezda uopšte. Naime, SDSS biblioteka sadrži samo 32 džina tipa K i M, koji su odabrani zato što odgovaraju zvezdanoj populaciji galaksija ranog tipa i klasičnim centralnim ovalima spiralnih galaksija. Sistematsko odstupanje biblioteka Stelib i Indo-US duž cele linije zadate funkcijom $y = x$, svedoči o nemogućnosti opisivanja galaksija sa klasičnim centralnim ovalom. Miles biblioteka zvezdanih spektara pokazuje izvesno odstupanje od SDSS biblioteke, ali je ono daleko manje. Najbolje slaganje sa SDSS bibliotekom postignuto je korišćenjem Elodie zvezdanih spektara. Pored grafičkih prikaza (iznad dijagonale), dati su i koeficijenti korelacije, vizuelno uvećani zavisno od stepena korelacije (ispod dijagonale). Odgovarajuća tabela C.1 u Dodatku C, pored merene kinematike pomoću pomenutih empirijskih biblioteka, sadrži nazive galaksija i njihove ekvatorijalne koordinate za manji uzorak od 657 galaksija (nezavisan od α -uzorka). Izvršen je još jedan test sistematike poređenjem sa nezavisnim izvorom

disperzija brzina. Idealan izbor je baza Hiperleda¹², s obzirom na to da je sačinjena iz različitih izvora i da su date disperzije računane različitim metodama. Na slici 3.8 date su (gausovske) disperzije računane korišćenjem pomenutih biblioteka za 172 galaksije koje se nalaze u manjem uzorku galaksija i Hiperleda bazi (Leda uzorak u daljem tekstu). Slika je istovetna sa slikom 3.7, samo je manji broj galaksija međusobno upoređen (172 galaksije), pošto baza Leda ne sadrži ceo ispitivan uzorak galaksija. Odgovarajući tabelarni prikaz dat je u Dodatku C (tabela C.2). Očigledno je da, u poređenju sa Leda uzorkom, simetrično odstupanje tačaka se javlja jedino kod Elodie i Miles empirijskih biblioteka i ovo odstupanje se može protumačiti kao slučajno rasejanje tačaka. Međutim, određivanjem λ parametra (slika 3.2), koje treba da prati povećanje ovog parametra sa povećanjem SNR-a, pojavilo se neočekivano ponašanje zvezdanih spektara iz Miles biblioteke - λ parametar se menjao sa drugačijim trendom i čak pokazivao degeneraciju, tako da je više različitih vrednosti ovog parametra davalo iste rezultate za različiti SNR. To može značiti samo jedno - nedovoljan broj zvezda i pojava zavisnosti od određenih tipova zvezda, kao posledica. Iz ovih razloga, u tezi je korišćena empirijska biblioteka Elodie za određivanje kinematike. Takođe, detaljnom analizom Miles i Elodie biblioteke na manjem uzorku galaksija, testiranih u različitim delovima spektra, ustanovljeno je da se korišćenjem Elodie biblioteke dobijaju manje greške računane disperzije brzina, nezavisno od tipa galaksija i nezavisno od spektralnog regiona unutar kojeg se izračunava disperzija brzina (Lalović, 2010). Takođe, u tezi su testirana i merenja uz pomoć sintetičke biblioteke sačinjene iz Stelib empirijske biblioteke kao osnove iz koje je pomoću modela konstruisano 39 spektara zvezdanih populacija širokog opsega starosti i metaličnosti sa ciljem da bude potpunija od svih empirijskih biblioteka (Tremonti et al., 2004).

¹²Hiperleda je baza podataka astronomskih objekata, prikupljenih iz radova cele astronomske zajednice. Sadrži preko tri miliona objekata, od čega su polovina galaksije (Makarov et al., 2014): <http://leda.univ-lyon1.fr>

Ovi sintetički spektri imaju rezoluciju $\text{FWHM} \approx 3 \text{ \AA}$ i talasni opseg 3200 - 9500 \AA , slično kao i SDSS spektri; starosti su od 0.005 - 10 Gyr i broje tri metaličnosti (subsolarnu, solaru i nadsolaru). Motivacija za testiranje sintetičkih spektara je pragmatična i naučno motivisana. Naime, ovih zvezdanih spektara ima za red veličine manje od Elodie zvezda, te se značajno ubrzava merenje kinematike α -uzorka galaksija.

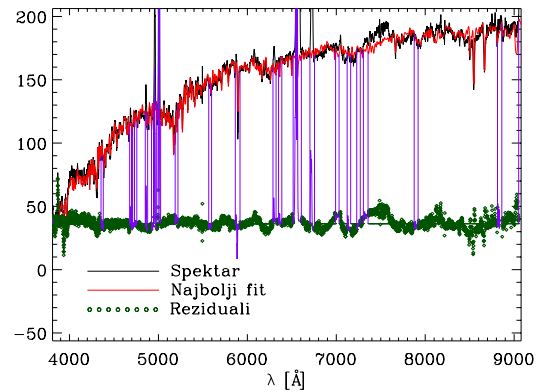

a) Pokrivenost Elodie bibliotekom.

$\sigma = 157.6 \text{ km/s } h_3 = 0 \ h_4 = -0.03$

b) Pokrivenost Indo-US bibliotekom.

$\sigma = 167.8 \text{ km/s } h_3 = 0.01 \ h_4 = -0.02$

Slika 3.5: Poređenje rezultata različitih biblioteka zvezdanih spektara na istoj galaksiji (NGC 2410). Levo - pokrivenost SDSS spektara; desno - rezultat fita pPXF programom. Emisione linije su maskirane. Dati su rezultati fita σ , h_3 i h_4 .

c) Pokrivenost Miles bibliotekom.

$$\sigma = 161.0 \text{ km/s } h_3 = 0.002 \ h_4 = -0.02$$

d) Pokrivenost Stelib bibliotekom.

$$\sigma = 133.3 \text{ km/s } h_3 = 0.03 \ h_4 = -0.2$$

Slika 3.6: Poređenje rezultata različitih biblioteka zvezdanih spektara na istoj galaksiji (NGC 2410). Levo - pokrivenost SDSS spektra; desno - rezultat fita pPXF programom. Emisione linije su maskirane. Dati su rezultati fita σ , h_3 i h_4 .

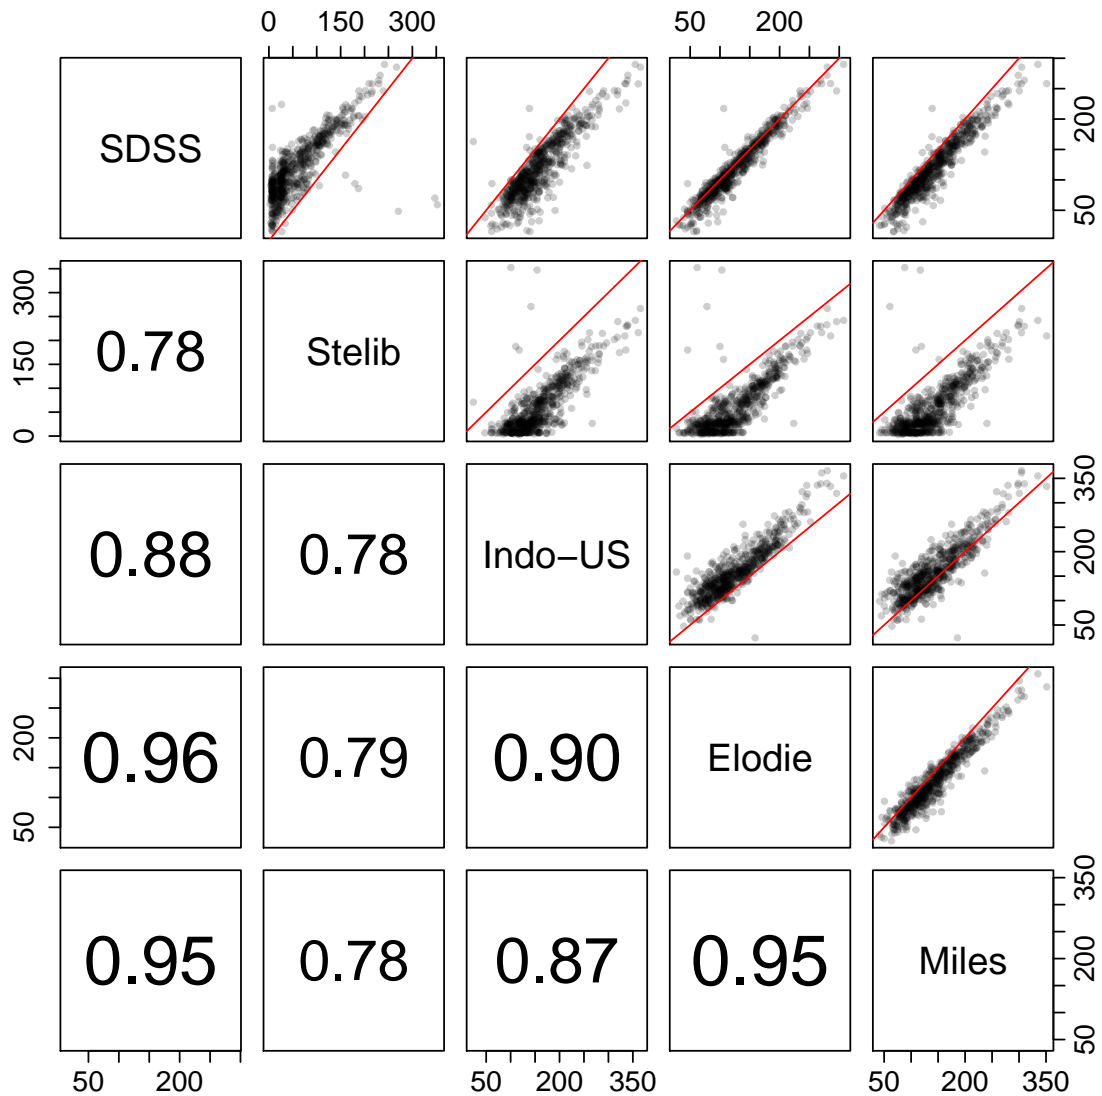

Naučna motivacija leži u činjenici da empirijskim bibliotekama nedostaju zvezde obogaćene α -elementima, pošto ih nema u bliini Sunca. Pojaćanje α -elementima raste linearno sa smanjenjem metaličnosti i stoga je znaćajno za ovale spiralnih galaksija i eliptiće galaksije (McWilliam, 1997). Dakle, postoji opravdana bojazan mogu li empi-

Tabela 3.1: Spisak korišćenih zvezdanih biblioteka. Kolone: (1) naziv biblioteke, (2) inicijalan broj zvezda u biblioteci, (3) finalni broj zvezda korišćenih u radu, (4) rezolucija u angstromima, (5) rezolucija u km/s i (6) opseg talasnih dužina zvezda.

rijske biblioteke podjednako dobro opisati galaksije različitih morfologija.

Poređenje disperzija brzina dobijenih pomoću empirijskih i sintetičkih spektara na α -uzorku pokazuju značajna odstupanja. Posebno je značajno poređenje sa SDSS rezultatima, pošto su oni dobijeni korišćenjem svega 32 džina tipa K i M, dominantnih u spektrima eliptičnih galaksija i centralnim ovalima spiralnih galaksija. Dakle, rezultati bi svakako trebalo da se slože za eliptične galaksije. Odstupanje je, međutim, primetno i kod ovog tipa galaksija. Ono bi se moglo objasniti nedostatkom zvezda tipičnih za klasične centralne ovale galaksija u Elodie biblioteci. Naime, zvezda sa α -obogaćenim elementima nema u blizini Sunca i stoga nedostaju u svim empirijskim bibliotekama, pa i u Elodie biblioteci. Pa ipak, eliptične galaksije pokazuju sistematsko odstupanje od $y = x$ linije (slika 3.9) za $\sigma \leq 200$ km/s. U visokom režimu disperzije brzina ($\sigma > 200$ km/s), odstupanje se može zanemariti, ali ovde se nalazi svega nekoliko galaksija, te se ne može izvesti zaključak o slaganju disperzija brzina velikih vrednosti. Poređenjem vrednosti merene disperzije brzina korišćenjem empirijske i sintetičke biblioteke na α -uzorku galaksija (slika 3.9), ustanovljeno je sistematsko potcenjivanje disperzije prilikom korišćenja sintetičkih zvezda. Kinematika profila, uključujući više momente raspodele brzina, dobijena korišćenjem sintetičke i empirijske biblioteke data je u tabeli D.1 u Dodatku D. Oni su upoređeni sa dostupnim merenjima iz SDSS (SDSS DR7), MPA-JHU

Slika 3.7: Poređenje rezultata merenja disperzija sa raznim bibliotekama zvezdanih spektara i posebno sa SDSS rezultatima. Na dijagonali su dati nazivi biblioteka; iznad dijagonale grafički prikaz međusobnih zavisnosti, a ispod dijagonale koeficijenti korelacije uvećani vizuelno zavisno od stepena korelacije. Crvena linija na graficima odgovara $y = x$ funkciji. Obe ose su disperzije brzina. Izmerena kinematika data je u tabeli C.1 u Dodatku C.

Slika 3.8: Poređenje rezultata merenja disperzija brzina sa dostupnim bibliotekama zvezdanih spektara, uključujući SDSS bazu i posebno sa Leda uzorkom. Uzorak je sveden na 172 galaksije, za koliko je nađena disperzija u bazi Leda. Na dijagonali su dati nazivi biblioteka; iznad dijagonale grafički prikaz međusobnih zavisnosti, a ispod dijagonale koeficijenti korelacije uvećani vizuelno zavisno od stepena korelacije. Crvena linija na graficima odgovara $y = x$ funkciji. Obe ose su disperzije brzina. Izmerena kinematika data je u tabeli C.2 u Dodatku C.

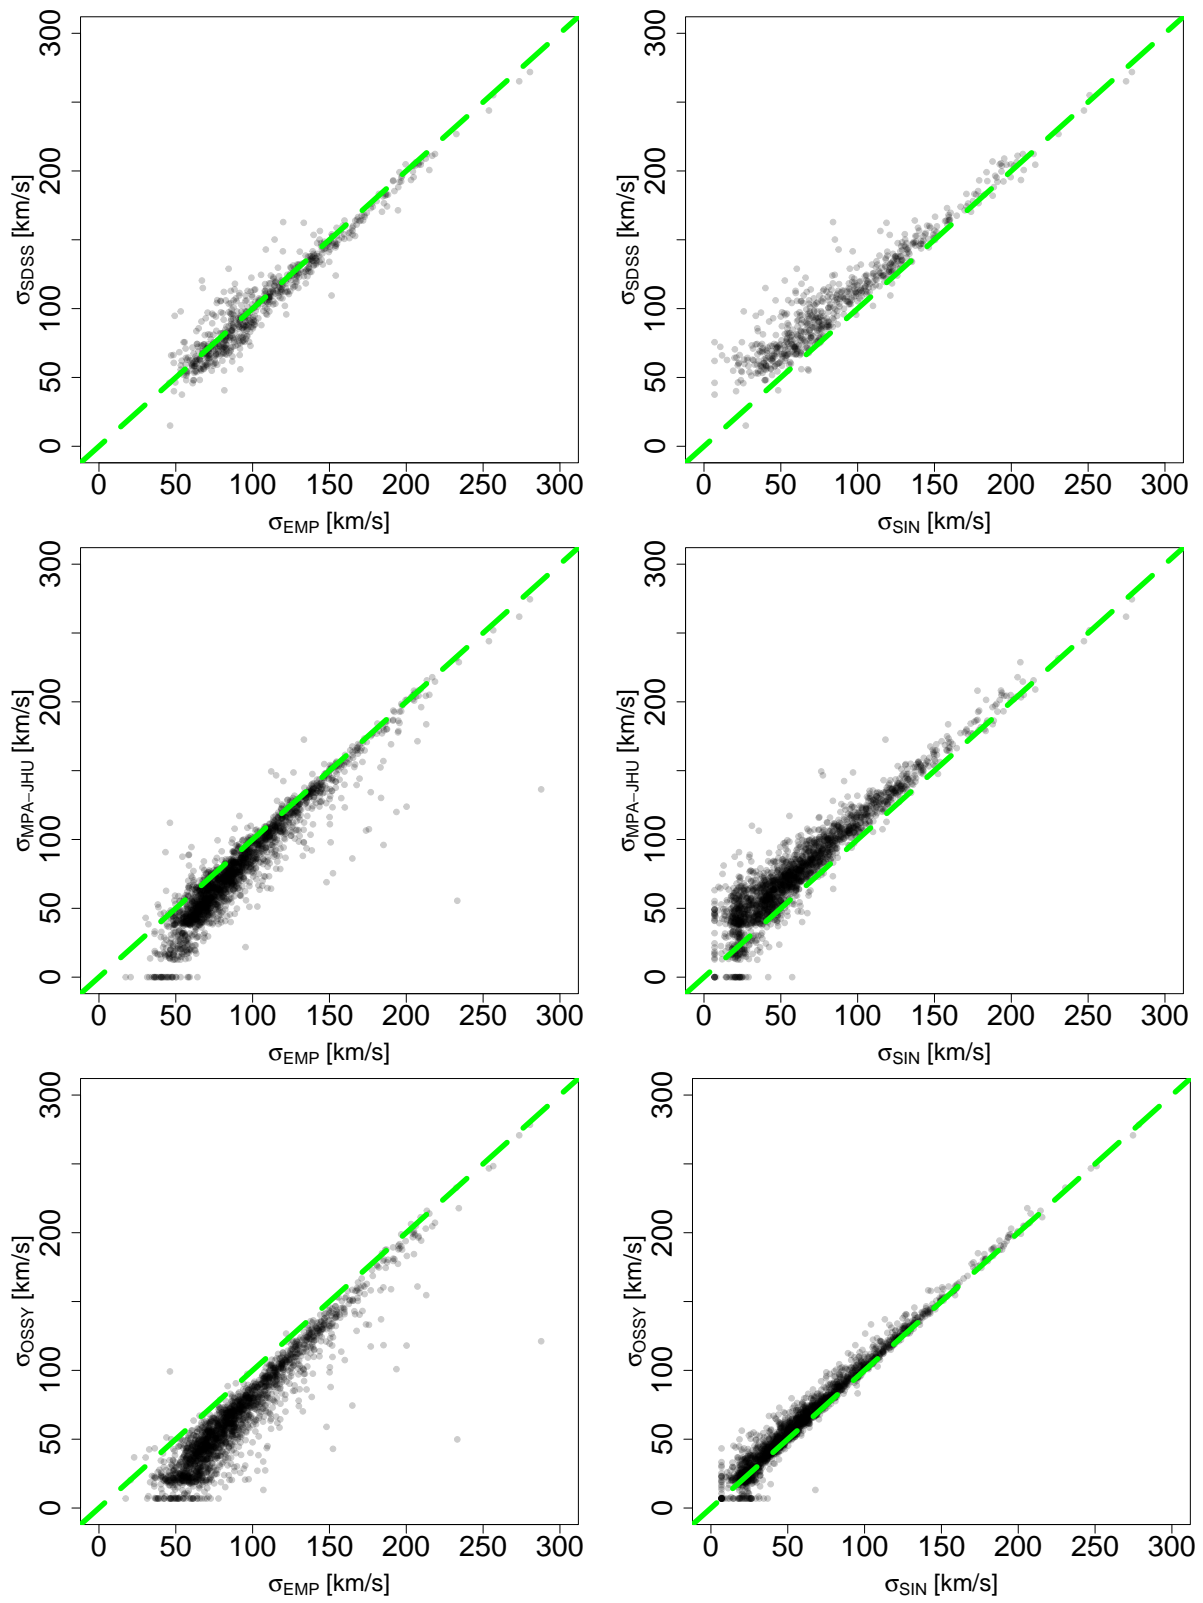

Slika 3.9: Poređenje rezultata merenja disperzije brzina korišćenjem empirijske (EMP) i sintetičke (SIN) biblioteke zvezdanih spektara, sa naznačenom morfologijom.

(Max Planck Institute for Astrophysics & Johns Hopkins University)¹³ i OSSY kataloga (Oh et al., 2011) i predstavljene su na slici 3.10. Poređenje je vršeno kako bi se ustanovilo slaganje sa postojećim rezultatima i radi testiranja sistematskog odstupanja sintetičke biblioteke na većem uzorku galaksija (α -uzorku). U levoj koloni pored se empirijski rezultati, a u desnoj sintetički. MPA-JHU koristi sintetičke spektre zasnovane na empirijskoj biblioteci Miles, dok OSSY takođe koristi sintetičke spektre, ali zasnovane na Stelib biblioteci spektara.

Slaganje je očekivano: sintetičke disperzije slažu se sa sintetičkim rezultatima, dok se empirijske slažu sa empirijskim (SDSS). Razlike koje se javlju kod manjih disperzija mogu se objasniti "kontaminacijom" spektara spiralnih galaksija (za spiralne galaksije karakteristične su manje disperzije brzina) emisijom linijama. Za manje vrednosti disperzija brzina nedostaju SDSS DR7 merenja, s obzirom na to da su vršena samo na galaksijama

¹³<http://wwwmpa.mpa-garching.mpg.de/SDSS/DR7/>

ranog tipa i klasičnim centralnim ovalima galaksija kasnog tipa. Razlog leži u činjenici da je za merenje disperzije brzina korišćena biblioteka sačinjena od 32 (K i M) džina, koji dominiraju sjajem galaksija ranog tipa. Ozbiljan problem je sadržan u činjenici pojave sistematskog odstupanja u odnosu na liniju zadatu funkcijom $y = x$, a ne slučajnog rasipanja tačaka. Najbolje slaganje sintetičkih rezultata sa OSSY bazom, može se objasniti računanjem kinematike iz iste zvezdane biblioteke (Stelib), sa tom razlikom da je potonjoj biblioteci dodat izvestan broj zvezdanih spektara iz Miles biblioteke. Slaganje empirijskih rezultata sa SDSS merenjima je ohrabrujuće, s obzirom na to da je SDSS koristio samo 32 zvezde i da su u pitanju različite biblioteke, a slaganje je jako dobro. Iz navedenih razloga, u krajnjoj statističkoj analizi biće korišćeni parametri (disperzija brzina i Likovi indeksi) dobijeni na osnovu empirijske Elodie biblioteke zvezdanih spektara (šesto poglavlje). U ovom i narednom poglavlju, nastavljeno je poređenje sintetičke i empirijske zvezdane biblioteke, kako bi se procenio uticaj upotrebe sintetičkih zvezdanih spektara na izračunavanje dinamičke mase (iz disperzije brzina) i korekciju Likovih indeksa (poglavlje 4). Primer pPXF fita u slučaju sintetičke i empirijske biblioteke za $\text{SNR} = 35$ (medijana SNR uzorka) dat je na slici 3.11. Oba fita su zadovoljavajuća, ali u sintetičkom slučaju izmerena disperzija je manja. Ovaj primer potvrđuje sistematsko potcenjivanje merene disperzije brzina upotrebom sintetičkih spektara.

Slika 3.10: Poređenje disperzije brzina α -uzorka sa postojećim rezultatima: SDSS (gore), MPA-JHU (sredina) i OSSY (dole) bazom, redom. Isprekidana linija je funkcija $y = x$. Levo su dati grafici disperzije brzina za empirijske biblioteke zvezdanih spektara "EMP", a desno za sintetičke "SIN".

Slika 3.11: Primer spektra jedne Sab galaksije iz α -uzorka (Alfafa 240255): najbolji pPXF fit dat je crvenom punom linijom, maskirane oblasti emisionih linija plavom isprekidanom linijom, a reziduali zelenim tačkama. Gore: empirijska biblioteka daje $\sigma = 120.5$ km/s, $h_3 = -0.0180$, $h_4 = 0.0421$ i $\chi^2 = 0.6$. Dole: sintetička biblioteka daje $\sigma = 107.9$ km/s, $h_3 = -0.0121$, $h_4 = 0.0116$ i $\chi^2 = 0.9$. Na donjem grafiku istaknut je i crveni pomak galaksije, iako je u oba slučaja spektar prikazan na $z = 0$.

3.3 Negausovska korekcija

U opštem slučaju kretanje zvezda u galaksiji je složeno: pored rotacije sa diskom (ukoliko ovaj postoji), prisutno je i nasumično kretanje zvezda u centralnom ovalu (disperzija brzina). Nasumično kretanje se može posmatrati kao dodavanje Gausijana pojedinačnih zvezda apsorpcionoj liniji koja se takođe može dobro opisati Gausijanom. Zbirni efekat je najčešće Gausijan širine zavisne od kretanja pojedinačnih zvezda, koje se može zamisliti kao nekakvo termalno kretanje (slika 3.12). Posmatrač vidi integralnu brzinu zvezda projektovanu na pravac posmatranja. Ova brzina ima dve komponente: radijalnu (ka centru galaksije) i tangencijalnu (upravno na ovaj pravac). U opštem slučaju postoje: asimetrična (koja se mere Gaus-Hermitovim h_3 koeficijentom) i simetrična (koja se mere Gaus-Hermitovim h_4 koeficijentom) odstupanja od Gausijana. Pozitivna (negativna) vrednost h_3 koeficijenta, opisuje koliko je raspodela brzina nagnuta ka većim (manjim) brzinama u odnosu na sistemsku brzinu. Pozitivne vrednosti h_4 koeficijenata ukazuju na to da je raspodela šira u krilima, a uža u centralnim delovima od Gausijana, dok se negativne vrednosti manifestuju pojavom platoa na vrhu Gausijana (ilustrovano na slici 3.1).

Disperzija brzina koristi se u mnogim relacijama za izračunavanje veličina koje se ne mogu direktno meriti, kao što su masa centralne crne rupe, dinamička masa galaksije itd. Ove veličine vezane su sa disperzijom brzina stepenim zakonom, čime se pojednostavljeno opisivanje LOSVD-a Gausijanom, koje unosi grešku u merenu disperziju brzina značajno uvećava (stepenovanjem se greška uvećava). Potrebno je primeniti korekcije za prisustvo viših momenata, kako bi se izbegle greške određivanja veličina izvedenih iz disperzije brzina (slika 3.13). Relacije koje koriguju radijalnu brzinu i disperziju brzina su (van der Marel & Franx, 1993):

$$V_{\text{kor}} = V^{\text{GH}} + \sqrt{3} h_3^{\text{GH}} \sigma^{\text{GH}} ; \quad (3.3.1)$$

Slika 3.12: Ilustracija doprinosa kretanja pojedinačnih zvezda širenju proizvoljne apsorpcione linije u spektru galaksije, koja nastaje kao zbir apsorpcionih linija pojedinačnih zvezda.

$$\sigma_{\text{kor}} = \sigma^{\text{GH}}(1 + \sqrt{6} h_4^{\text{GH}}), \quad (3.3.2)$$

gde indeks GH označava vrednosti parametara Gaus-Hermitovog polinoma, σ_{kor} korigovanu vrednost disperzije, a h_3 i h_4 su Gaus-Hermitovi koeficijenti. Primera radi, iz α -uzorka izdvojene su galaksije ranog tipa (eliptične i sočivaste) da demonstriraju korekciju disperzije (slika 3.14). Na slici (3.14) prikazan je odnos korigovane i nekorigovane (Gausovske) disperzije sa stepenom sa kojim disperzija brzina figuriše u relacijama određivanja virijalne mase (jednačina 3.3.4) i mase crne rupe (jednačina 3.3.5). Virijalna teorema za stacionarni zvezdani sistem glasi (Bertin et al., 2002):

$$\frac{G\Upsilon L_*}{R_e} = K_V \sigma_0^2, \quad (3.3.3)$$

gde je Υ zvezdani odnos mase i sjaja (engl. mass-to-light ratio), G gravitaciona konstanta, R_e efektivni radijus, a σ_0 centralna disperzija. $K_V(n)$ je u opštem slučaju funkcija Sersikovog indeksa (Taylor et al., 2010). Na osnovu ove jednačine, dinamička masa (M_{dyn}) je data izrazom:

$$M_{\text{dyn}} = K_V \frac{\sigma_0^2 R_e}{G}. \quad (3.3.4)$$

Ovde je zanemarena funkcionalna zavisnost $K_V(n)$, i K_V je približno konstanta, što i jeste slučaj kod galaksija ranog tipa, gde je $n \approx 4$. Naravno, treba imati na umu da je izraz za

virijalnu masu (jednačina 3.3.4) izveden uz zanemarivanje rotacije, tako da predstavlja donju granicu mase. Značajno je pomenuti da ona važi za disperziju procenjenju na 1/8 delu efektivnog radijusa, ali u režimu niskog crvenog pomaka efektivni radijus eliptičnih galaksija je oko 30", što je uzimajući u obzir optičko vlakno prečnika od 3" zapravo 1/10 deo efektivnog radijusa i približno je validna i bez aperturne korekcije. Ipak, tačna formula sa korigovanom disperzijom brzina biće primenjena u krajnjoj analizi rezultata (šesto poglavlje).

Takozvana M-sigma relacija (Kormendy & Ho, 2013) koja povezuje dinamičku masu sa centralnom disperzijom data je relacijom:

$$\log\left(\frac{M_{\text{BH}}}{M_{\odot}}\right) \propto \beta \log(\sigma_0), \quad (3.3.5)$$

gde je BH indeks koji označava crnu rupu (engl. black hole), β koeficijent koji u pionirskom radu Ferrarese & Merritt (2000) iznosi $\beta = 4.8 \pm 0.5$. Ona omogućava procenu mase centralne crne rupe na osnovu merene disperzije brzina i može se primeniti kod galaksija koje imaju klasičan centralni oval.

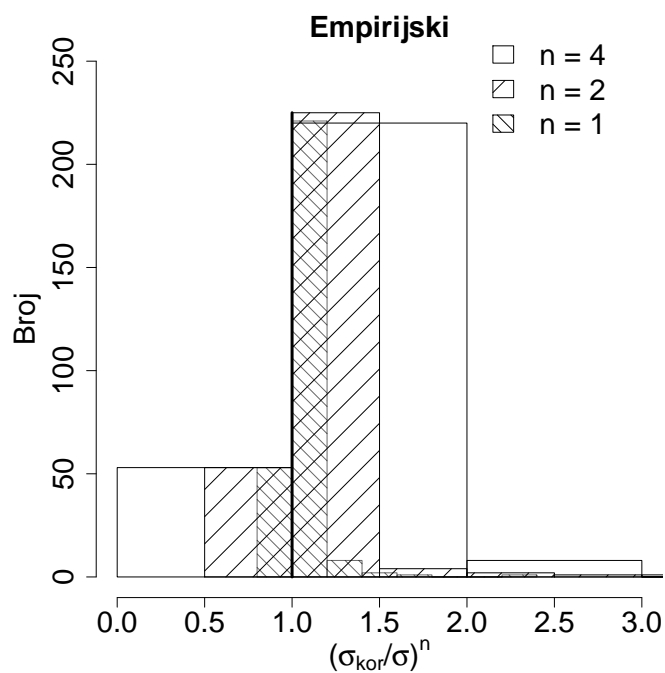

Sa slike 3.14 vidi se da postoji trend ka desnom "repu" histograma, što znači da je procenjena masa sistematski manja kada se primeni aproksimacija Gausijanom. U srednjem, odnos količnika, a samim tim i virijalna masa povećava se 13% za korigovanu vrednost disperzije.

3.3.1 Anizotropija kod galaksija različitih morfoloških tipova

Gaus-Hermitovi koeficijenti mogu se dovesti u vezu sa različitim modelima nastanka galaksija i zato su značajni za razumevanje nastanka i evolucije galaksija. Prema studiji orbita u eliptičnim galaksijama, Dekel et al. (2005) pokazuju da kod eliptičnih galaksija dominiraju radijalne orbite ($h_4 > 0$). Upravo ovakvo ponašanje je primećeno na poduzorku galaksija ranog tipa iz α -uzorka. Naime, binovanjem morfološkog tipa galaksija datog kontinuiranom verovatnoćom ($0 \leq \text{pES0} \leq 1$), primećen je trend uvećanja Gaus-

Slika 3.13: Odnos korigovane (jednačina 3.3.2) i nekorigovane (Gausovske) disperzije brzina sa istaknutom morfologijom za α -uzorak galaksija.

Slika 3.14: Stepen količnika korigovane (jednačina 3.3.2) i nekorigovane disperzije prikazuje veličinu greške koja se unosi aproksimacijom raspodele brzina Gausijanom.

Hermitovog koeficijenta h_4 sa porastom verovatnoće pripadanja galaksijama ranog tipa (slika 3.15). Granična vrednost $pES0 = 0.5$ na slici 3.15 predstavljena je sivom isprekidanom vertikalnom linijom: sa leve strane ($pES0 < 0.5$) su galaksije kasnog tipa, a sa desne ($pES0 \geq 0.5$) galaksije ranog tipa. Drugim rečima, što je morfologija galaksije sličnija eliptičnim galaksijama, to je Gaus-Hermitov koeficijent h_4 veći, odnosno *orbite zvezda postaju dominantno radialne*. Gaus-Hermitov koeficijent h_3 ne menja se zavisno od morfologije, dok se h_4 menja tako što se *povećava* idući od galaksija kasnog tipa do galaksija ranog tipa (slika 3.15). Ovakvo ponašanje prisutno je nezavisno od korišćene biblioteke, pa ipak u empirijskom slučaju $h_4 > 0$, dok je u sintetičkom slučaju $h_4 < 0$. Odgovarajuća tabela 3.2 daje vrednosti Gaus-Hermitovih koeficijenata u zavisnosti od binovanog morfološkog tipa galaksija, sa 1σ greškama i ukupnim brojem tačaka u svakom binu.

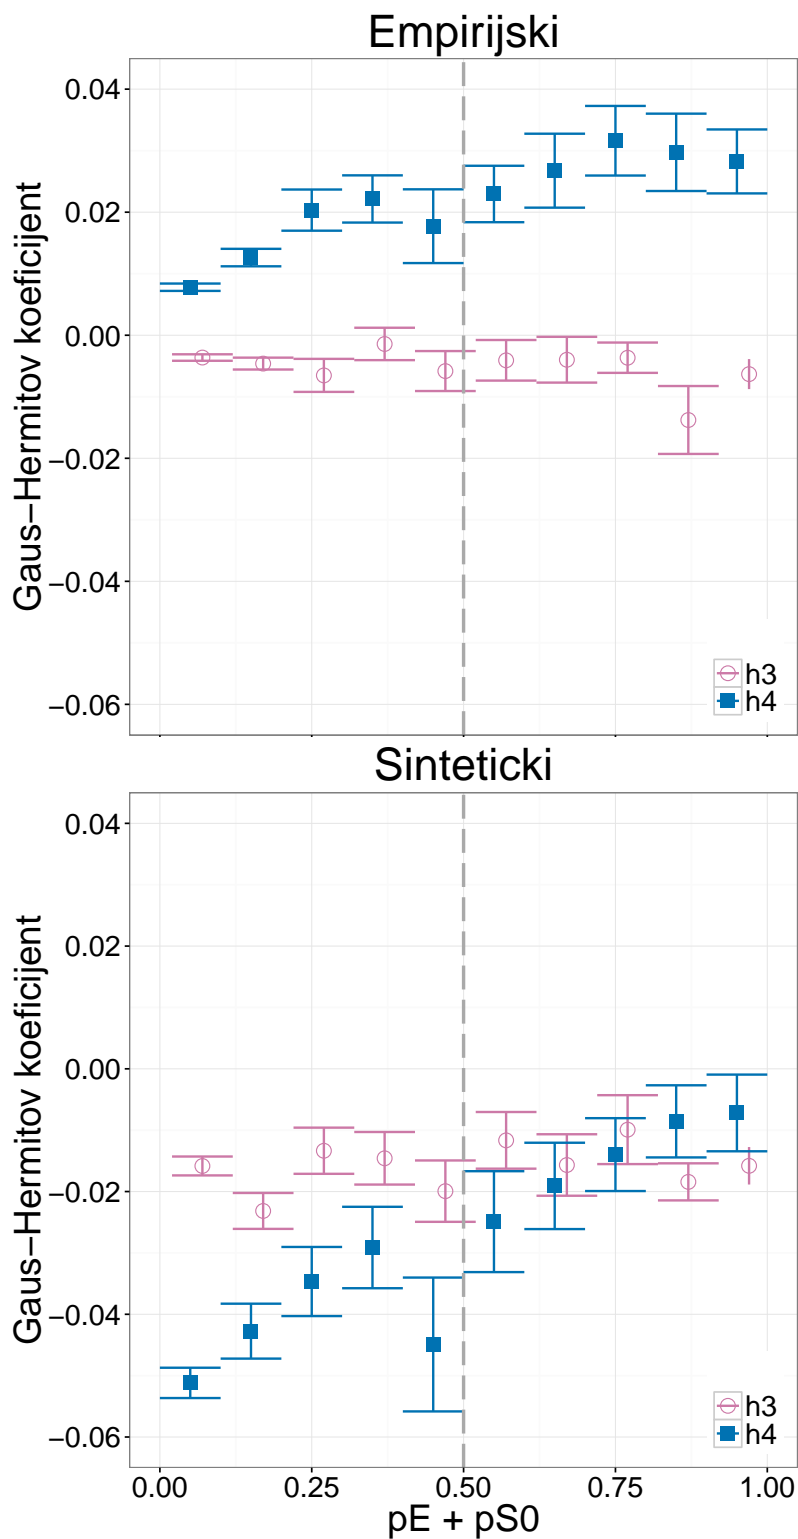

Na slici 3.16 prikazana je raspodela Gaus-Hermitovog koeficijenta h_4 nalik histogramu, pomoću tzv. grafika gustine (engl. kernel density). Prednost prikaza raspodele promenljive korišćenjem gustine umesto klasičnog histograma, leži u velikoj osetljivosti histograma na veličinu bina prilikom binovanja. Funkcija gustine (engl. kernel density estimate ili skraćeno, KDE) je neparametarski prikaz funkcije gustine verovatnoće slučajne promenljive i zasniva se na pretpostavci da se svaka funkcija nepoznate gustine f može predstaviti kao suma n kernela¹⁴, odnosno "razbiti" na pojedinačne kernele:

$$f_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right), \quad (3.3.6)$$

gde je K kernel¹⁵, x centralne vrednosti kernela, a x_i tačke u okolini centralne tačke x , koje ulaze u širinu kernela h (engl. bandwidth). Širina kernela predstavlja veličinu "peglanja" raspodele. Ovo je ujedno i jedini parametar koji je potrebno odrediti, mada

¹⁴Kernel je proizvoljna funkcija, a najčešće se koriste: uniformna, trougaona, dvotežinska, trotežinska, Epanečikova i normalna. Ipak, najoptimalnija je normalna raspodela (Gausijan) i ona je korišćena u ovom radu.

¹⁵Kernel je po definiciji ne-negativna funkcija čiji je integral jednak jedinici, a srednja vrednost nuli.

Slika 3.15: Trend Gaus-Hermitovih koeficijenata sa morfologijom: h_3 (crveni prazni krugovi) ne pokazuje zavisnost od morfološkog tipa, dok h_4 (plavi puni kvadrati) raste sa povećanjem verovatnoće pripadanja galaksije ranom tipu ($pES0$). Granična vrednost $pES0 = 0.5$ deli galaksije kasnog ($pES0 < 0$) i ranog ($pES0 \geq 0$) tipa i prikazana je isprekidanom, vertikalnom linijom. Gore: empirijski slučaj. Dole: sintetički slučaj. Vrednosti koeficijenata h_3 i h_4 su date u tabeli 3.2.

Tabela 3.2: Tabela vrednosti Gaus-Hermitovih koeficijenta (h_3 i h_4) i njihovih 1σ grešaka prema kontinuiranom morfološkom tipu, binovanom sa korakom od 0.5. U poslednjoj koloni dat je ukupan broj tačaka u svakom binu. Gore: empirijski slučaj. Dole: sintetički slučaj.

postoje jako dobra već usvojena rešenja zasnovana na prirodi samih podataka (Sheather & Jones, 1991), što ovaj prikaz čini superiornim u odnosu na klasičan histogram. Ukratko, svaka tačka raspodele koju ne znamo, a pokušavamo predstaviti, može se zamisliti kao kernel određene širine. Kada saberemo sve pojedinačne kernele dobijamo gustinu raspodele. Grafik gustine na slici 3.16 prikazuje razlike u raspodelama galaksija svih morfoloških tipova (E, S0, Sab i Scd) u empirijskom i sintetičkom slučaju, redom. Interesantno je primetiti kako je kod eliptičnih galaksija h_4 pozitivan (u oba slučaja), dok je kod sočivastih galaksija h_4 pozitivan samo u empirijskom slučaju. Statistički testovi vršeni na h_4 parametru u sledećem potpoglavlju pokazaće da eliptične i lentikularne galaksije potiču iz iste raspodele. Pored same raspodele Gaus-Hermitovih koeficijenata galaksija različitih morfoloških tipova, određena su prva četiri momenta (s_1, s_2, s_3 i s_4) oba Gaus-Hermitova koeficijenta (tabela 3.3 i 3.4), prema standardnim formulama, sa težinama inverzno proporcionalnim kvadratu greške, reflektujući različit SNR galaksija¹⁶:

$$s_1 \equiv \bar{x} = \sum_{i=1}^N \frac{w_i x_i}{W}, \text{ gde je } W = \sum_{i=1}^N w_i, \quad (3.3.7)$$

$$s_2 = \sqrt{\frac{\sum_{i=1}^N w_i (x_i - \bar{x})^2}{d}}, \text{ gde je } d = W - \frac{\sum_{i=1}^N w_i^2}{W}, \quad (3.3.8)$$

$$s_3 = \frac{\sum_{i=1}^N w_i (x_i - \bar{x})^3}{d \times s_2^3} \text{ i} \quad (3.3.9)$$

$$s_4 = \frac{\sum_{i=1}^N w_i (x_i - \bar{x})^4}{d \times s_2^4} - 3. \quad (3.3.10)$$

U empirijskom slučaju, analizirajući vrednosti momenta Gaus-Hermitovog koeficijenta h_4 (slika 3.16 i tabela 3.3), možemo zaključiti sledeće:

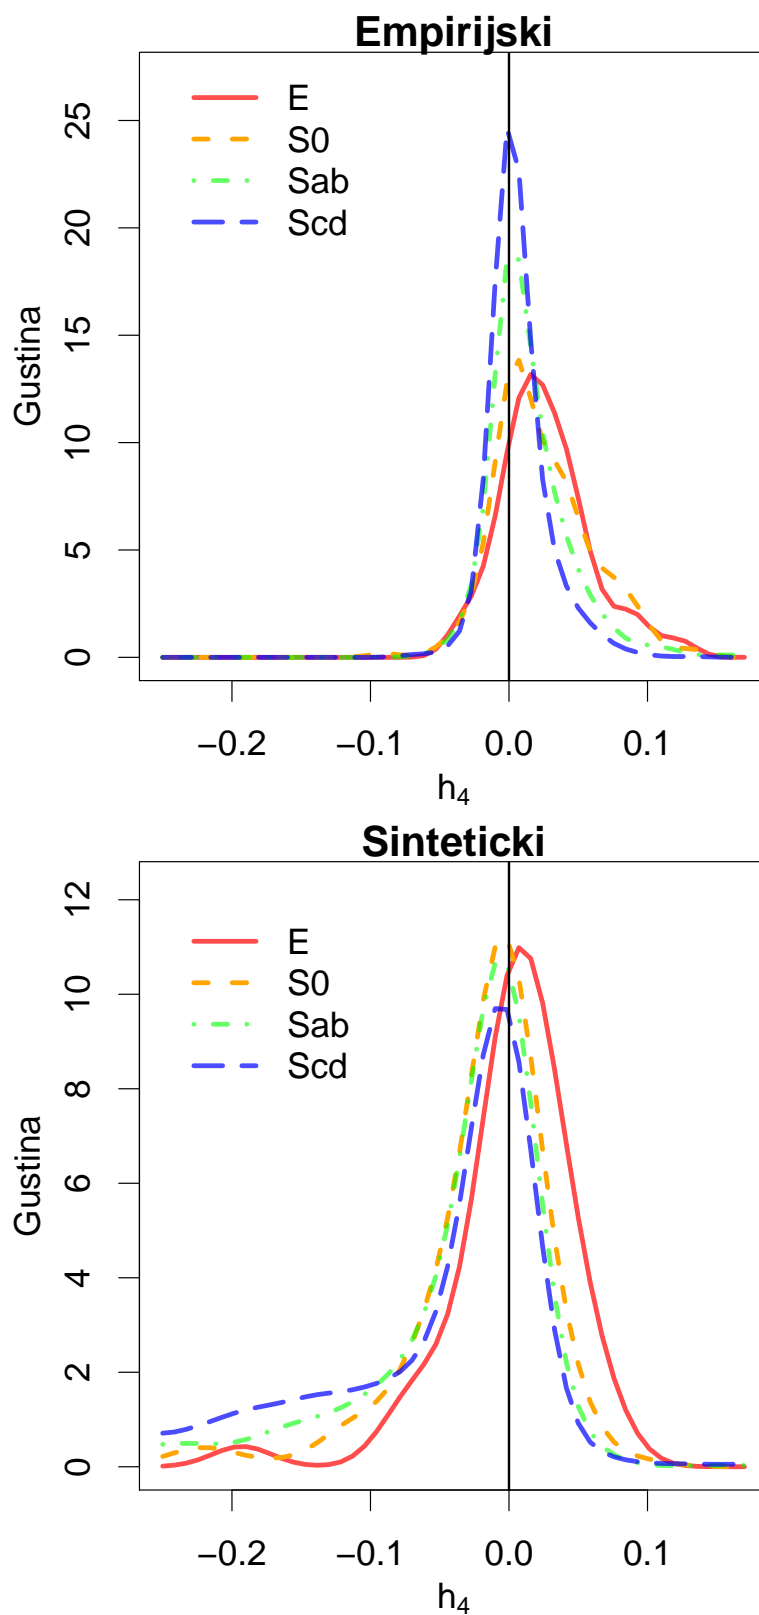

- i) svi tipovi galaksija imaju maksimum h_4 koeficijenta na *pozitivnoj* strani, implicirajući dominaciju radijalnih orbita,
- ii) $s_4 > 0$ nezavisno od morfološkog tipa implicirajući zašiljenu raspodelu u svim slučajevima i

¹⁶<http://www.nag.co.uk/numeric/fl/manual/pdf/G01/g01aaf.pdf>

iii) repovi raspodele opisani s_3 parametrom pokazuju da se koeficijent asimetrije h_4 koeficijenta povećava od Scd do E galaksija (sa izuzetkom sočivastih galaksija S0).

Grafik sa sintetičkom bibliotekom (slika 3.15) pokazuje nešto drugačije ponašanje h_4 parametra. Samo za eliptične galaksije (E) srednja vrednost h_4 koeficijenta je pozitivna ($s_1 > 0$), dok je za ostale morfološke tipove ova srednja vrednost negativna ($s_1 < 0$), ali je $s_4 > 0$ nezavisno od morfolološkog tipa galaksije (sa izuzetkom Scd galaksija), implicirajući i u ovom slučaju dominaciju radijalnih orbita (tabela 3.4).

Anizotropije su značajne, jer ulaze u rešavanje Džinsove (Jeans) jednačine kod eliptičnih galaksija (Samurović, 2007), ali i kod spiralnih galaksija, npr. kod Mlečnog puta (Samurović & Lalović, 2011).

Slika 3.16: Raspodela h_4 koeficijenta za različite morfologije galaksija, od $pES0 = 0$ do $pES0 = 1$. Gore: empirijski slučaj. Dole: sintetički slučaj.

Tabela 3.3: Prva četiri momenta h_3 i h_4 raspodele: srednja vrednost, standardna devijacija, koeficijent asimetrije i koeficijent spljoštenosti, za galaksije svih morfoloških tipova za *empirijsku biblioteku*. Broj objekata po tipu dat je sa "N". Ukupan broj galaksija je nešto manji od celog α -uzorka i broji 2169 galaksija, pošto su izuzete one galaksije sa graničnim vrednostima koeficijenata $|h_3| = |h_4| = 0.3$. Ovo su fiksirane, ekstremne vrednosti programa pPXF i stoga nepouzidane.

3.4 Statistički testovi

S obzirom na ulogu h_4 koeficijenta u nastanku i evoluciji galaksija, izvršen je niz statističkih testova sa ciljem da se nađu relacije i trendovi ovog parametra sa morfologijom. Svi testovi vršeni su posebno na galaksijama ranog (E0) i kasnog (S) tipa, ali i podgrupama koje su formirane limitiranjem kontinuiranih verovatnoća (E, S0, Sab, Scd). Ključ razumevanja različitih morfoloških tipova iz verovatnoća prema radu Huertas-Company et al. (2011), dat je u tabeli 3.5.

Tabela 3.5: Formiranje grupa različitih morfoloških tipova prema radu Huertas-Company et al. (2011). Osim dva kanonska tipa: galaksije ranog i kasnog tipa, mogu se dobiti i posebno eliptične, sočivaste i spiralne galaksije Sa+Sb i Sc+Sd.

"Galaksije ranog tipa" (engl. "Early") == E0	pE + pS0
"Galaksije kasnog tipa" (engl. "Late") == S	pSab + pScd
"Eliptične" == E	pE ≥ pS & pE > pS0
"Lentikularne" == S0	pS0 ≥ pS & pS0 ≥ pE
"Spiralne Sa & Sb" == Sab	pS > pES0 & pSab > pScd
"Spiralne Sc & Sd" == Scd	pS > pES0 & pSab ≤ pScd

Primenjena su tri statistička testa na parametar h_4 sa ciljem ispitivanja hipoteze da li različiti morfološki tipovi potiču iz iste raspodele ili, prosto rečeno, imaju li zajedničko poreklo i to su: i) Anderson-Darling test (AD u daljem tekstu; Scholz & Stephens (1987); Darling (1957); Anderson & Darling (1952)), ii) Kolmogorov-Smirnov test (KS u daljem tekstu; Hoel (1971)) i iii) Kramer-fon-Misiz test (KFM u daljem tekstu; Anderson (1962)). AD test je neparametarski test i može se primeniti na proizvoljnu raspodelu (ne samo normalnu) i ključna prednost u odnosu na poznatiji KS test jeste veća osetljivost na razlike u "repovima" raspodela koje se porede. Poredeći AD i KS test Engmann &

Darling (2011) zaključuju da AD test u slučajevima uzoraka manje veličine postiže istu predikcionu moć kao KS test na većim uzorcima, te da je "AD test moćniji od KS testa u detekciji svih potencijanih razlika među uzorcima koji potiču iz dve različite raspodele". Treći statistički test, često korišćen u literaturi je KFM test. To je takođe neparametarski test, primenljiv na proizvoljnu raspodelu, ali daje manje težine repovima raspodele, što ga takođe čini manje osetljivim.

Sva tri testa porede tzv. kritičnu (teorijsku) vrednost izračunatu pod nultom hipotezom da dva uzorka dele istu raspodelu sa posmatranom (empirijskom) vrednošću, sa *unapred zadatom verovatnoćom* (nivo poverenja sa kojim se može odbaciti nulta hipoteza) $\alpha = 0.05$. Svi oni porede empirijske raspodele, koristeći različite kriterijume. Takođe, svi daju *a posteriori verovatnoću* ili *p-vrednost*, koja mora biti manja od *a priori verovatnoće* (α) ukoliko je nulta hipoteza tačna.

U oba slučaja, empirijskom i sintetičkom, primenjena su sva tri testa sa ciljem da ustanove potiču li h_4 raspodele za različite morfološke tipove (E0 nasuprot S, E nasuprot S0, Sab nasuprot Scd) iz istih populacija (populacija sa istim raspodelama). Ukoliko je odgovor potvrđan, možemo zaključiti da upoređeni tipovi galaksija imaju zajedničko poreklo.

U empirijskom slučaju (tabela 3.6), testovi saglasno odbacuju nultu hipotezu za galaksije iz dve grupe (E0 nasuprot S i Sab nasuprot Scd), tako da možemo zaključiti da potiču iz različitih raspodela. U slučaju eliptičnih nasuprot sočivastih galaksija (E nasuprot S0), s obzirom na to da je posmatrana verovatnoća manja od kritične, možemo zaključiti da ova dva tipa potiču iz iste raspodele. U sintetičkom slučaju (tabela 3.7), sa druge strane, sve suprotstavljene morfologije (E0 nasuprot S, E nasuprot S0, Sab nasuprot Scd) potiču iz različitih raspodela. Vidimo da je empirijska biblioteka superiorna u odnosu na sintetičku u detekciji zajedničkog porekla eliptičnih i sočivastih galaksija.

Tabela 3.6: Statistički rezultati tri testa (AD, KFM i KS) za Gaus-Hermitov koeficijent h_4 . Testovi su izvršeni za empirijski slučaj. Kolone: 1) naziv testa, 2) kritična (teorijska) vrednost, 3) posmatrana (empirijska) vrednost, 4) p-vrednost. Broj galaksija odgovarajućeg tipa dat je u zagradi uz morfološki simbol galaksija (E0, S, E, S0, Sab, Scd). Za opis morfoloških simbola korišćenih ovde, pogledati tabelu 3.5. Ukupan broj galaksija dat u tabeli je 2169, umanjen u odnosu na α -uzorak za one galaksije koje su dostigle ekstremne vrednosti koeficijenata $|h_3| = |h_4| = 0.3$.

Poglavlje 4

Indeksi jačine linija

U ovom poglavlju biće predstavljeni rezultati merenja Likovih indeksa (engl. Lick indices) na spektrima galaksija iz SDSS DR7, koji obuhvataju 3'' centra galaksija. Dakle, ovo su strogo *centralni indeksi* i odnose se samo na centralne ovale galaksija. Kako su galaksije pretežno kasnog tipa i visokom stopom formiraju zvezde ne postoje adekvatni hemijski modeli koji ih opisuju, pošto su indeksi i modelovanje istih koncipirani da opišu galaksije ranog tipa. Pa ipak, indeksi su značajan parametar za opisivanje galaksija izveden iz spektara i nisu korišćeni u literaturi za statističku analizu, koja će biti primenjena u ovoj tezi upotpunjena Likovim indeksima u šestom poglavlju. Takođe, u postojećoj literaturi nisu vršene korekcije indeksa za efekat širenja apsorpcionih linija Gaus-Hermitovim polinomima, već Gausijanima. Rezultate ću uporediti sa postojećim merenjima i dovesti u direktnu vezu sa starošću i metaličnošću galaksija određenih drugom metodom. U pitanju je modelovanje celog galaktičkog spektra sintetičkim zvezdanim spektrima, različitih starosti i metaličnosti. Kao jedan od rezultata modelovanja, dobijaju se disperzije brzina. Međutim, s obzirom na to da se javlja sistematsko odstupanje merenih disperzija brzina u odnosu na vrednosti dobijene korišćenjem empirijske biblioteke zvezdanih spektara Elodie, modelovane starosti i metaličnosti biće upotrebljene samo kako bi se dobili optimalni Likovi indeksi, kao najbolji indikatori starosti i metaličnosti galaksija.

Poglavlje je koncipirano na sledeći način: u potpoglavlju 4.1 definisan je Likov sistem spektralnih indeksa; u potpoglavlju 4.2 predstavljen je su relevantne korekcije indeksa; u potpoglavlju 4.3 dato je poređenje sa rezultatima drugih, i diskutuju se razlike; u potpoglavlju 4.4 opisan je metod izračunavanja starosti i metaličnosti iz celih spektara galaksija, nasuprot indeksima koji se mere u uskim regionima oko apsorpcionih linija; u potpoglavlju 4.5 odabrana su dva indeksa koji će nadalje služiti kao indikatori starosti i metaličnosti.

4.1 Likov sistem indeksa

Likov sistem apsorpcionih indeksa je veoma popularan i u upotrebi od davne 1972. godine, kada je Sandra Faber sa saradnicima započela projekat izučavanja zvezdanih populacija globularnih jata i galaksija ranog tipa. U narednim godinama snimljeni su spektri velikog broja zvezda svih tipova, patuljaka i džinova, ali i bliskih galaksija sa rezolucijom od približno $\text{FWHM} = 8.6 \text{ \AA}$, u spektralnom opsegu $\sim 4000 \text{ \AA} - 6200 \text{ \AA}$. Faber et al. (1985) su definisali 21 spektralni indeks, kojima su kasnije dodata još četiri indeksa neosetljiva na emisiju gasa (Worthey & Ottaviani, 1997). Definicije svih 25 indeksa koje čine Likov sistem, mogu se naći na web sajtu koji održava Guy Worthey¹. Ove talasne dužine su date u vazduhu. Kako su talasne dužine SDSS spektara vakuumske, u tabeli E.1 date su talasne dužine u vakuumu, određene pomoću IDL-ove procedure `airtovac`. Vrednosti spektralnih indeksa sadrže informaciju o zastupljenosti raznih hemijskih elemenata. Odabrani su tako da budu osetljivi na efektivnu temperaturu (T_{eff}), površinsku gravitaciju (g) i metaličnost zvezde (Z).

Indeks je zapravo površina određene apsorpcione linije (npr. H_{β} ili Fe_{4531}) ispod prave određene dvema tačkama tzv. pseudokontinuumu (nalik ekvivalentnoj širini).² Naime, sa

¹<http://astro.wsu.edu/worthey/html/system.html>

²Nije prava ekvivalentna širina, pošto su granice unutar kojih se meri fiksne i krila linije mogu "izaći" iz regiona, usled instrumentalne rezolucije ili širenja linije prouzrokovanog disperzijom brzine galaksije.

obe strane regiona samog indeksa (centralni region), definisani su regioni pseudokontinuumu (plavi i crveni), u kojima se prosto srednje vrednosti fluksa uzimaju kao tačke kroz koje prolazi prava linija pseudokontinuumu (slika 4.1). Ovo nije pravi kontinuum, jer je definisan "lokalno" za svaki indeks i otuda naziv pseudokontinuum. Centralni region samog indeksa odabran je brižljivo radi izučavanja širokih apsorpcionih linija eliptičnih galaksija i, zahvaljujući niskoj rezoluciji, značajno umanjuje doprinos disperzije brzina širenju linije.

S obzirom na to da jačine apsorpcionih linija nose informaciju o zastupljenosti hemijskih elemenata, dele se na atomske (ekvivalentne širine) i molekulske (magnitudo). Po definiciji:

$$I_a = \int_{\lambda_{c1}}^{\lambda_{c2}} \left(1 - \frac{S(\lambda)}{C(\lambda)} \right) d\lambda \quad \text{i} \quad (4.1.1)$$

$$I_m = -2.5 \log_{10} \left(\frac{\int_{\lambda_{c1}}^{\lambda_{c2}} (S(\lambda)/C(\lambda)) d\lambda}{\lambda_{c1} - \lambda_{c2}} \right), \quad (4.1.2)$$

gde su λ_{c1} i λ_{c2} granice centralnog regiona indeksa, $C(\lambda)$ lokalni pseudokontinuum:

$$C(\lambda) = S_b \frac{\lambda_r - \lambda}{\lambda_r - \lambda_b} + S_r \frac{\lambda - \lambda_b}{\lambda_r - \lambda_b}, \text{ gde je} \quad (4.1.3)$$

$$S_b = \frac{\int_{\lambda_{b1}}^{\lambda_{b2}} S(\lambda) d\lambda}{\lambda_{b2} - \lambda_{b1}}, S_r = \frac{\int_{\lambda_{r1}}^{\lambda_{r2}} S(\lambda) d\lambda}{\lambda_{r2} - \lambda_{r1}} \text{ i} \quad (4.1.4)$$

$$\lambda_b = \frac{\lambda_{b1} - \lambda_{b2}}{2}, \lambda_r = \frac{\lambda_{r1} - \lambda_{r2}}{2}. \quad (4.1.5)$$

Talasne dužine λ_{b1} , λ_{b2} i λ_{r1} , λ_{r2} su granice plavog i crvenog pseudokontinuumu, redom. Lista indeksa, sa centralnim regionom indeksa, kao i plavim i crvenim granicama pseudokontinuumu, data je u tabeli E.1 u Dodatku E.

Likovi indeksi u ovoj tezi izračunati su pomoću novog programa napisanog u IDL-u u tu svrhu. Greške su računane kao u radu Cardiel et al. (1998), sa razlikom da je disperzija (u Å/pikselu) varijabilna u linearnoj skali (konstantna u logaritamskoj skali). Po definiciji,

slučajna greška atomskih indeksa je:

$$\sigma[I_a] = \sigma \left[\int_{\lambda_{c1}}^{c2} \frac{S(\lambda)}{C(\lambda)} d\lambda \right], \quad (4.1.6)$$

ali se u praksi mora prevesti u zbir po pikselima:

$$\sigma[I_a] \propto \sigma \left[\sum_{i=1}^N \frac{S_i(\lambda)}{C_i(\lambda)} \theta_i \right], \quad (4.1.7)$$

gde je N broj piksela unutar centralnog indeksa, a θ_i promenljiva spektralna disperzija (u Å/pikselu). Odgovarajući izraz za grešku molekulskih indeksa je:

$$\sigma[I_m] = 2.5 \frac{\log e}{10^{-0.4I_m}} \frac{1}{\lambda_{c2} - \lambda_{c1}} \sigma[I_a]. \quad (4.1.8)$$

4.2 Korekcije Likovih indeksa

Spektralni indeksi zahtevaju spektre visokog SNR-a, te je potrebno utvrditi kolike su relativne greške indeksa za opseg SNR-a α -uzorka. Iz rada Cardiel et al. (1998) preuzeta je slika 4.2 koja prikazuje relativne greške 21 indeksa zavisno od SNR-a u slučaju jedne sjajne zvezde. Relativne greške padaju ispod 50% za srednji SNR uzorka ($\text{SNR} \geq 35$) i čak ispod 20%, osim u slučaju dva indeksa (Ca_{4227} i TiO_1). Tek na $\text{SNR} > 80$, greške padaju ispod 10%. Nažalost, to je ujedno i najveći SNR α -uzorka.

Upravo iz ovog razloga, potrebno je eliminisati sve druge potencijalne izvore grešaka. Preciznom merenju indeksa prethode dva koraka: čišćenje galaktičkog spektra od emisionih linija (zabranjeni prelazi i rekombinacione linije) i svođenje spektra na Likovu rezoluciju. Emisione linije kontaminiraju mnoge regione unutar kojih se mere indeksi, ali i pseudokontinuum (npr. crveni pseudokontinuum Mg b linije može biti kontaminiran sa [NI]; Goudfrooij & Emsellem (1996)). Za kontaminaciju su odgovorne pre svega Balmerove linije, a posledica je sistematsko umanjeње vrednosti indeksa. Pri proceni starosti iz H_β indeksa, ukoliko se ne ukloni emisija jonizovanog gasa, uneće se greška usled

Slika 4.1: Ilustracija nekoliko spektralnih indeksa iz rada Henry & Worthey (1999): površina apsorpcione linije unutar osenčenog regiona je vrednost indeksa. Prikazana je za nekoliko različitih indeksa. Isprekidana linija između dve kratke horizontalne linije sa svake strane apsorpcione linije definiše pseudokontinuum. Na slici se isti indeksi porede za nekoliko različitih tipova zvezda, kako bi se videlo u kojoj meri se vrednost indeksa (osenčena površina) menja zavisno od promene spektralnog tipa zvezde.

Slika 4.2: Relativne greške merenja spektralnih indeksa zavisne od SNR spektra iz rada (Cardiel et al., 1998). Obe ose su logaritamске. Za $\text{SNR} \geq 35$, što je srednji SNR analiziranog α -uzorka, relativne greške indeksa padaju ispod 50%, sa izuzetkom CN1 i Ca4227 indeksa.

umanjene procene indeksa, odnosno pogrešno će se proceniti veća starost zvezdanih populacija. U ovu svrhu korišćen je program *Gandalf* (Sarzi et al., 2006), koji prvo meri kinematiku zvezda kako bi je potom fiksirao i fitovao set emisionih linija Gausijanima određene talasne dužine i širine (npr. Balmerove linije moraju sve imati jednaku disperziju brzina, tj. širenje). Program određuje amplitude (težine) emisionih linija i zatim oduzima najbolji (u smislu χ^2 statistike) emisioni spektar (uticaj gasa), čime ostaje samo apsorpcioni spektar koji potiče od zvezda. Ovo je spektar na kome se mogu meriti apsorpcione linije, ali nakon što se dovede u isti sistem u kome su definisani Likovi indeksi (Likov sistem indeksa).

Jačina apsorpcione linije (indeksa) zavisi, između ostalog i od instrumentalne rezolucije. Naime, što je rezolucija manja, to će i indeks biti manji, pošto je definisan u određenom *fiksiranom* regionu (tabela E.1 u Dodatku E), a sa povećanjem instrumentalnog širenja krila linija "izlaze" iz regiona, ostavljajući manju površinu unutra. Dakle, da bismo

sveli SDSS spektre na Likov sistem, moramo ih degradirati na nižu rezoluciju Lik/IDS instrumenta. Svako optičko vlakno SDSS spektrografa ima rezoluciju promenljivu sa talasnom dužinom (σ_{pix}), koja je data u šestoj ekstenziji `fits` fajla za svaki objekat. To je zapravo srednje kvadratno odstupanje (engl. root-mean-square; skraćeno rms) rezolucija po pikselu, koja se mora pomnožiti veličinom piksela u jedinicama talasne dužine, kako bi se dobila rezolucija u talasnoj dužini:

$$\sigma_{\lambda} = \sigma_{\text{pix}} * \ln(10) * \lambda_{\text{pix}} * 0.0001, \quad (4.2.1)$$

gde je λ_{pix} talasna dužina za dati piksel, σ_{pix} njegova disperzija, a 0.001 korak sa kojim su logaritamski binovani SDSS spektri. Ako je σ_{Lik} spektralna rezolucija Likovog sistema, širina Gausijana kojim treba konvoluirati ceo SDSS spektar, kako bi se degradirao na Likovu rezoluciju je:

$$\sigma = \sqrt{\sigma_{\text{Lik}}^2 - \sigma_{\text{SDSS}}^2}, \quad (4.2.2)$$

gde je σ_{SDSS} zapravo σ_{λ} iz prethodne jednačine, a σ_{Lik} je data u radu Worthey & Ottaviani (1997).³ Spektar varijanse (1σ greška fluksa) mora se podeliti sa vektorom čiji svaki element odgovara broju piksela koji su "ušli" u Gausijan (širina Gausijana) u svakoj tački spektra.

Nakon merenja indeksa, potrebno je korigovati vrednosti na disperziju brzina. Naime, indeksi su definisani na zvezdanim spektrima čija je disperzija nula. Sa druge strane, spektri galaksija imaju nenulte disperzije i ne mogu se dekonvoluirati. Ovaj efekat širenja apsorpcionih linija posledica je kretanja velikog broja zvezda i dovodi do sistematskog smanjenja vrednosti indeksa, pošto ima isti efekat kao degradiranje rezolucije. Potrebno je na svakom integralnom zvezdanom spektru koji najbolje opisuje galaktički spektar izmeriti indeks i zatim ponoviti merenje na istom spektru proširenom u istom iznosu u kome je proširen galaktički spektar (disperzija brzina).

³Tačna posmatrana FWHM spektralna rezolucija data je u radu Worthey & Ottaviani (1997) i jednostavno se može linearno interpolirati, tako da svakoj tački u spektru odgovara Gausijan određene širine.

Korekcije se onda mogu izvršiti sledećim formulama:

$$I_{\text{kor}} = I_{\text{pos}} * I(0)/I(\sigma), \text{ za atomske indekse i} \quad (4.2.3)$$

$$I_{\text{kor}} = I_{\text{pos}} + I(0) - I(\sigma), \text{ za molekulske indekse,} \quad (4.2.4)$$

gde je I_{kor} korigovana vrednost indeksa, I_{pos} Likov indeks meren na galaktičkom spektru očišćenom od emisije i dovedenom na crveni pomak $z = 0$, $I(0)$ indeks meren na spektru zvezde, a $I(\sigma)$ indeks meren na spektru zvezde proširenom disperzijom brzina galaksije (σ). Ova korekcija se može izvršiti nakon što pPXF program odredi najbolji integralni zvezdani spektar kao linearnu kombinaciju zvezdanih spektara koji najviše doprinose sjaju date galaksije $I(0)$, a zatim se ovaj spektar konvoluira odgovarajućim Gaus-Hermitovim polinomom $I(\sigma)$.⁴ Korigovani Likovi indeksi dati su u tabelama: F.1, F.2 i F.3 i F.4 u Dodatku F, za empirijsku i sintetičku biblioteku, redom, zajedno sa modelovanom starošću i metaličnošću [Fe/H]. Nešto jednostavnija korekcija i vremenski manje zahtevna, opisana je u radu Kuntschner (2004). Oni daju empirijske izraze korekcije apsorpcionih indeksa za različite kombinacije disperzije brzina i Gaus-Hermitovih koeficijenata. Njihove korekcije primenljive su na galaksije starije od 3 Gyr. Samurović (2009) računa korekcije na sličan način opisan u ovoj tezi, uzimajući u obzir merene vrednosti viših momenata LOSVD funkcije i propagirajući 1σ neodređenosti fluksa. Opisane korekcije izvedene su za opšti slučaj, dakle važe za proizvoljne vrednosti Gaus-Hermitovih parametara, za razliku od onih datih u radu Kuntschner (2004).

Postoji još jedna korekcija, koju nije moguće izvršiti zbog nedostatka Likovih zvezda u SDSS DR7 bazi spektara i koja stoga nije primenjena u ovoj tezi. Naime, kod spektara zvezda Likovog sistema fluks nije kalibrisan, već normalizovan na kalibracionu lampu. Razlike u kontinuumu SDSS i Likovih spektara zbog drugačije kalibracije manifestovaće se pojavom sistematskih pomeraja u vrednostima indeksa. Da bi se ovo ispravilo, potrebno je odrediti iznos pomeraja indeksa u odnosu na originalni Likov sistem, tako

⁴detaljno opisano u trećem poglavlju.

što se nađu zajedničke zvezde i indeksi novog sistema dovedu na nultu tačku Likovog sistema.

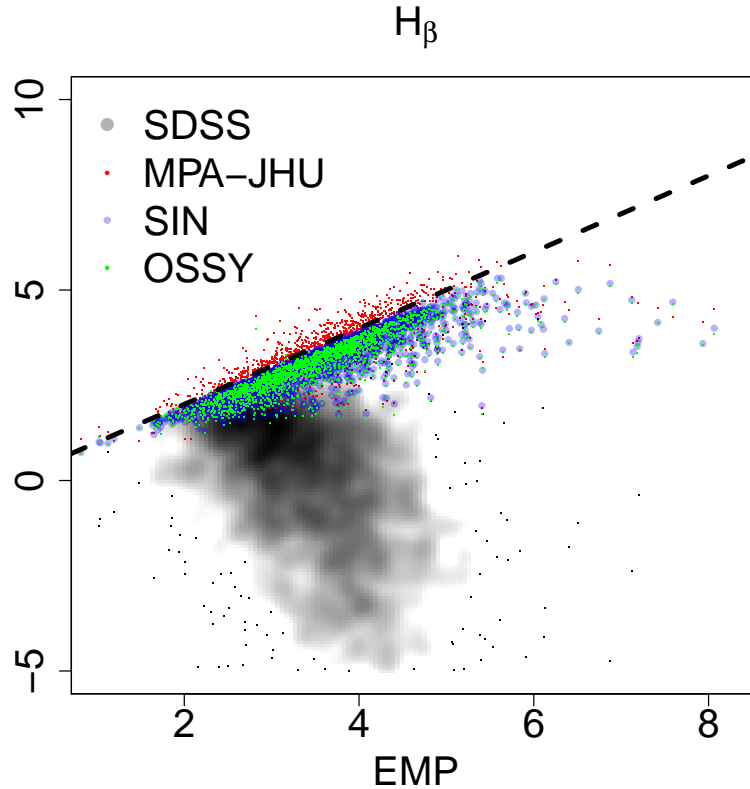

4.3 Poređenje sa postojećim rezultatima

Likovi indeksi za galaksije iz α -uzorka iz njihovih SDSS spektara, računati su od strane nekoliko grupa: SDSS⁵, MPA-JHU⁶ i OSSY⁷. SDSS indeksi su računati na spektrima SDSS rezolucije, što ih čini sistematski manjim. SDSS spektri su korigovani na emisione linije tako što je primenjena metoda odstranjivanja autsajdera (engl. 3 σ clipping). Druge korekcije nisu rađene. MPA-JHU grupa je svela spektre na Likovu rezoluciju, a emisione linije tretirala Gausijanima proizvoljne širine koji su oduzimani. Sa druge strane, OSSY grupa je izvršila sve korekcije osim svođenja na nultu tačku Likovog sistema. Disperzije su korigovali ne za svaki spektar pojedinačno, kako je urađeno u ovom radu, već su korekciju računali za disperziju brzina sa određenim korakom. Na slici 4.3 prikazano je slaganje sa postojećim merenjima H_{β} indeksa, uključujući i sintetički slučaj. Preostala 24 indeksa data su na slikama F.1, F.2, F.3, F.4, F.5 i F.6 u Dodatku F. Sva poređenja vršena su sa empirijskim merenjima (EMP na x-osi) i to su redom: SDSS (sive tačke), MPA-JHU (crvene tačke), naša sintetička merenja SIN (plavi kružići) i konačno, OSSY merenja (zelene tačke). Razlike su očekivane: SDSS indeks je sistematski manji, pošto nije sveden na Likovu rezoluciju, ali i zbog različitog tretmana emisije. MPA-JHU merenja se dobro slažu, čak i za veće vrednosti indeksa, gde je značajan doprinos korekcije disperzije brzina. Ovo je posledica boljeg slaganja MPA-JHU merene disperzije sa disperzijom brzina merenom u ovom radu u empirijskom slučaju (slika 3.10). Rezultati OSSY grupe se zapravo dobro slažu, ako se uzme u obzir da su dobijeni na sintetičkim zvezdanim spektrima, koji sistematski potcenjuju disperziju brzina. Njihovo slaganje sa sintetičkim

⁵<http://classic.sdss.org/dr7/algorithms/speclinefits.html>.

⁶http://wwwmpa.mpa-garching.mpg.de/SDSS/DR7/SDSS_indx.html.

⁷<http://gem.yonsei.ac.kr/ossy/htmls/database.php>.

Slika 4.3: Merenje H_β Likovog indeksa u empirijskom slučaju nasuprot merenjima SDSS grupe (siva zona nastala uzimanjem gradijenta tačaka zavisno od njihove koncentracije radi bolje vidljivosti), MPA-JHU grupe (crvene tačke), koristeći sintetičku biblioteku (SIN, plavi kružići) i OSSY grupe (zelene tačke). Isprekidana linija je funkcija $y = x$.

slučajem (plave tačke) je jako dobro i posledica je korišćenja sintetičkih spektara. Dakle, najznačajniji je efekat prisustva emisijonih linija, kod onih indeksa koji su kontaminirani emisijom. Drugi značajan efekat je korekcija na disperziju brzina zavisna od veličine same disperzije. Ona je prisutna kod svih indeksa, ali je umanjena kod indeksa koji zahvataju širi region spektra. Konkretno, kod molekulskih indeksa (npr. CN_1 i CN_2) je zanemarljiva (slika F.1). U slučaju OSSY grupe korišćeni su sintetički spektri koji sistematski umanjuju disperziju brzina, te su i same korekcije manje, odnosno indeksi su sistematski potcenjeni. Ovaj efekat je daleko izraženiji kod "užih" indeksa gvožđa, npr. Fe_{5709} i Fe_{5782} (slika F.5).

4.4 Starost i metaličnost

Postojeći programi poput `Ez_ages` programa (Schiavon, 2007; Graves & Schiavon, 2008)⁸ ne sadrže mlade zvezde u dovoljnom broju da bi se direktno iz Likovih indeksa mogla proceniti starost i metaličnost galaksija. α -uzorkom dominiraju galaksije aktivne u smislu formiranja zvezda, tako da su odgovarajuće dominantne zvezde vruće (tipa O, B i A). Drugačiji pristup je modelovanje celog spektra galaksije (engl. full spectrum fitting) linearnom kombinacijom jednodimenzionalnih zvezdanih populacija (skraćeno SSP) prirovoljne starosti i metaličnosti. U tu svrhu korišćen je program `ulyss` (Koleva et al., 2008, 2009). Optimalni najbolji zvezdani spektar traži mesto najbolje χ^2 vrednosti, u mreži starosti i metaličnosti dobijene interpolacijom pojedinačnih zvezdanih populacija PEGASE.HR modela⁹ (Le Borgne et al., 2004)¹⁰. Minimizira se vrednost:

$$\chi^2 = \sum_{N_\lambda} \frac{[F_i - P_{1p}(T_i(\text{SFH}) \times L(v, \sigma, h_3, h_4) + P_{2q})]^2}{\Delta F_i^2}, \quad (4.4.1)$$

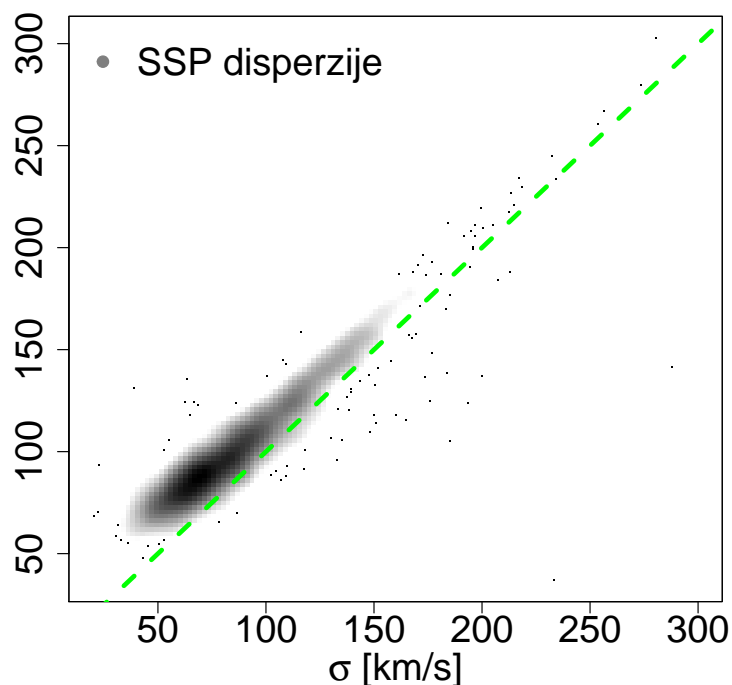

gde je $L(v, \sigma, h_3, h_4)$ raspodela brzina duž linije vida, F_i i ΔF_i fluks i njegova neodređenost, $T_i(\text{SFH})$ je linearna kombinacija jednodimenzionalnih zvezdanih populacija i predstavlja *funkciju starosti i metaličnosti*, a P_{1p} i P_{2q} su multiplikativni i aditivni Ležandrovi polinomi reda p i q , respektivno i koriste se za korekciju oblika kontinuum. Ovo je generalizacija pPXF programa korišćenog za određivanje disperzija brzina. Koncept je istovetan i jedina razlika je u tome što se umesto biblioteke zvezdanih spektara (bilo empirijskih bilo sintetičkih) koriste jednodimenzionalne zvezdane populacije različitih starosti i metaličnosti.

Zvezdani spektri su zasnovani na Elodie biblioteci empirijskih spektara, korišćenju u

⁸http://w.astro.berkeley.edu/~graves/ez_ages.html

⁹Program PEGASE.2 pravi sintetičke spektre modelovanjem empirijskih Elodie zvezdanih spektara, u opsegu metaličnosti $-2.7 < [\text{Fe}/\text{H}] < +0.4$ i starosti od 10^7 do 2×10^9 godina, koristeći Salpeterovu IMF (Salpeter, 1955).

¹⁰<http://www2.iap.fr/pegase/pegasehr/index.html>

Slika 4.4: Poređenje Gausovske disperzije dobijene pomoću empirijske Elodie i sintetičke Elodie biblioteke. Disperzija brzina u km/s, data je na obe ose.

ovom radu za izračunavanje disperzija brzina. Primenom spektrofotometrijskog modela PEGASE.2 (Fioc & Rocca-Volmerange, 1997), sintetisana je zvezdana populacija u opsegu metaličnosti $[\text{Fe}/\text{H}] = (-2.7, +0.4)$ u domenu $\lambda = (4000, 6800) \text{ \AA}$. Program `ulyss` istovremeno određuje kinematiku i parametre zvezdane populacije (starost i metaličnost). Merene disperzije brzina su Gausijani, a radi uspešnog modelovanja zvezdanog kontinuuma mora se koristiti visok multiplikativni polinom (stepen = 35). Posledica korišćenja *sintetičkih spektara* je pojava sistematskog odstupanja merenih disperzija sa trendom povećanja od oko 20% u odnosu na empirijske disperzije brzina izračunate korišćenjem iste biblioteke zvezdanih spektara, samo empirijskih (slika 4.4).

S obzirom na to da su disperzije brzina sistematski veće u slučaju sintetičkih spektara

koje koristi program, u ovoj tezi će rezultujuće starosti i metaličnosti biti korišćene samo kako bi se dobili najbolji Likovi indeksi osetljivi ili (samo) na starost ili (samo) na metaličnost i koji će u daljoj analizi biti tretirani kao indikatori starosti i metaličnosti. Dakle, neće se koristiti same vrednosti starosti i metaličnosti, već indeksi koji najbolje korelišu sa njima, jer iako su apsolutne vrednosti parametara zvezdane populacije možda sistematski izmenjene, njihove relativne vrednosti su dobre i omogućavaju međusobno poređenje. U daljoj analizi neće biti bitno koliko je neka galaksija stara, već *koliko je stara u odnosu na druge galaksije* iz uzorka.

4.5 Optimalni spektralni indeksi

Likovi indeksi su birani u uskom opsegu oko apsorpcionih linija, tako da umanje uticaj prašine i kontaminaciju drugim linijama na pojedinačne linije, a da istovremeno budu osetljivi na starost i/ili metaličnost. Problem je spajanje (engl. blend) više apsorpcionih linija u svakom spektru galaksije kao integralnom spektru pojedinačnih zvezda koje se ne može odstraniti, ali se pažljivim odabirom i kombinovanjem linija može svesti na najmanju meru. Različiti indeksi u različitoj meri korelišu sa starošću i metaličnošću zvezdanih populacija, a cilj je naći takve indekse (ili njihovu kombinaciju) koja korelišu samo sa starošću, ali ne i sa metaličnošću i obrnuto. Konačno, u kontekstu modela zvezdane populacije, dati indeksi se mogu dovesti u direktnu vezu sa starošću i metaličnošću. Ipak, ovde će biti korišćena samo osobina osetljivosti indeksa na parametre zvezdane populacije, zbog skromnog slaganja disperzija brzina empirijske i sintetičke biblioteke. Kada se izračunaju koeficijenti korelacije Likovih indeksa sa starošću i metaličnošću dobijenih iz PEGASE.HR modela, mogu se izdvojiti indeksi osetljivi samo na jedan od ova dva parametra zvezdane populacije (starost i metaličnost). Pored H_β indeksa, i ostali Balmerovi indeksi ($H_{\gamma,A}$ i $H_{\delta,A}$ i njihovi "širi" pandani $H_{\gamma,F}$ i $H_{\delta,F}$) dobro korelišu sa starošću, ali skoro jednako dobro korelišu i sa metaličnošću, te su stoga izostavljeni.

Tabela 4.1: Koeficijenti korelacije Likovih indeksa sa starošću i metaličnošću. U kolonama su dati redom: (1) Fe_{5015} , (2) Fe_{5270} , (3) Fe_{5335} , (4) srednji indeks gvožđa korišćen u literaturi $\langle \text{Fe} \rangle$, (5) novi indeks gvožđa $\langle \text{Fe} \rangle'$ i (6) H_β .

	Fe_{5015}	Fe_{5270}	Fe_{5335}	$\langle \text{Fe} \rangle$	$\langle \text{Fe} \rangle'$	H_β
Starost	0.40	0.48	0.34	0.43	0.48	-0.71
Metalichnost	0.58	0.61	0.51	0.60	0.67	-0.37

Indeksu $\langle \text{Fe} \rangle = 1/2 (\text{Fe}_{5270} + \text{Fe}_{5335})$ može se dodati i Fe_{5015} , nepravедno izostavljen zbog moguće kontaminacije emisionim linijama. Novi indeks $\langle \text{Fe} \rangle' = 1/3 (\text{Fe}_{5015} + \text{Fe}_{5270} + \text{Fe}_{5335})$ značajno pojačava korelaciju sa metaličnošću (tabela 4.1). Ovo su tzv. indeksi gvožđa, koji dobro korelišu sa metaličnošću. Mg_2 indeks je izostavljen, jer iako ima najviši koeficijent korelacije sa metaličnošću (0.72), značajno koreliše i sa starošću (0.63). Sa druge strane, H_β indeks mnogo bolje koreliše sa starošću nego sa metaličnošću, čime se jednaki efekti koje ove dve pojave utiskuju u spektre mogu razlučiti. Za korelaciju H_β indeksa sa starošću, videti Matteucci (2012).

Na slici 4.5 prikazane su korelacije između indeksa, koji će zbog ovih svojih svojstava biti korišćeni u daljoj analizi. Koeficijent korelacije odabranog indeksa gvožđa $\langle \text{Fe} \rangle'$ sa modelovanom metaličnošću iz programa `ulyss` je veliki, a istovremeno ovaj indeks slabo koreliše sa modelovanom starošću i H_β indeksom, kao njenim indikatorom. Ovo je važno zbog degeneracije između starosti i metalichnosti, koja je zbog male korelacije dva odabrana Likova indeksa $\langle \text{Fe} \rangle'$ i H_β veoma mala (koeficijent korelacije ova dva indeksa iznosi 0.38).

Dakle, u daljoj analizi biće korišćena samo dva spektralna indeksa $\langle \text{Fe} \rangle'$ i H_β , zbog značajne korelacije sa metaličnošću, odnosno starošću, redom i nepostojanja značajne

međusobne korelacije. Koeficijenti korelacije ova dva indeksa, i posebno indeksa gvožđa (Fe_{5015} , Fe_{5270} i Fe_{5335}) koji ulaze u izraz za izabrani indeks gvožđa $\langle \text{Fe} \rangle'$, dati su u tabeli 4.1. Kako bi se dobili indeksi čije su greške relativno male, pošto se pri izračunavanju koeficijenta korelacije ne mogu koristiti greške, izvršeno je 3σ odstranjivanje autsajdera. U ovom poglavlju, odabrani su optimalni indeksi $\langle \text{Fe} \rangle'$ i H_β , kao dobri indikatori metaličnosti i starosti, redom i koji će biti korišćeni u krajnjoj statističkoj analizi α -uzorka galaksija u šestom poglavlju. Ova dva parametra, iako predstavljaju fundamentalne osobine galaksija, nisu korišćena u prethodnim radovima slične tematike.

Poglavlje 5

Modelovanje površinskog sjaja galaksija

Modelovanje površinskog sjaja galaksija pruža informacije o koncentraciji sjaja i stoga može poslužiti za grubu morfološku klasifikaciju galaksija na kanonske tipove: galaksije ranog i kasnog tipa. Naime, površinski sjaj galaksija ranog tipa je više koncentrisan, nego što je to slučaj sa galaksijama kasnog tipa. Opisivanje površinskog sjaja Sersikovim zakonom, daje dva parametra koja ulaze u izraz za dinamičku masu: Sersikov indeks i efektivni radijus galaksije. Iz ovog razloga, biće urađeno modelovanje Sersikovim zakonom programom Galfit, tretirajući galaksije kao jedinstvene strukture (jednokomponentno modelovanje). Dinamička masa je fundamentalna osobina galaksija i biće korišćena u završnoj analizi u šestom poglavlju.

U ovom poglavlju modelovanje površinskog sjaja biće urađeno na slikama iz SDSS DR8 fotometrijske baze podataka, pošto su one date bez pozadine. Oduzimanje pozadine je poseban problem i nije razmatran ovde. Veoma je teško automatizovati oduzimanje pozadine za veliki broj galaksija, ali je urađeno za jednu blisku galaksiju NGC 2841 u radu (Samurović et al., 2015), gde je takođe urađeno detaljno modelovanje površinskog sjaj galaksije, na način opisan u ovoj tezi. (Meert et al., 2016) uradili su dekompozi-

ciju površinskog sjaja na SDSS DR7 galaksijama, od kojih ima 2014 zajedničkih sa α -uzorkom. Zbog nepotpune pokrivenosti α -uzorka, dekompozicija je ponovljena u ovom poglavlju.

Poglavlje je koncipirano na sledeći način: u potpoglavlju 5.1 opisana je priprema slike za dekompoziciju profila sjaja galaksije, koja je složena i sastoji se iz nekoliko koraka; u potpoglavlju 5.2 detaljno je opisana urađena dekompozicija, a u poglavlju 5.3 rezultati se porede sa postojećim kataloškim merenjima i diskutuje značaj strukturnih parametara za dalju analizu.

5.1 Analiza površinskog sjaja galaksije

Analiza sjaja galaksije je složen postupak i sastoji se iz nekoliko koraka:

- Identifikacija i izdvajanje odgovarajuće galaksije sa slike i izračunavanje osnovnih parametara: momenata sjaja (položaj, velika i mala poluosa, pozicioni ugao), FWHM itd.
- Izračunavanje površinskog sjaja galaksije i određivanje poboljšanih momenata sjaja (položaj, velika i mala poluosa, pozicioni ugao itd.).
- Izračunavanje fotometrije (magnituda) svih objekata; podela na galaksije i zvezde radi određivanja slike tačkastog izvora (PSF, engl. point spread function) sa liste najsjajnijih zvezda.
- Jednodimenzionalno linearno fitovanje azimutalno usrednjenog profila površinskog sjaja radi procene početnih parametara za dvodimenzionalno fitovanje ili dekompoziciju.
- Dekompozicija dvodimenzionalne slike galaksije.

U cilju modelovanja površinskog sjaja galaksija α -uzorka, korišćeno je nekoliko programa, jer ne postoji jedinstven program koji bi mogao automatski uraditi dekompoziciju. Za pravljenje kataloga objekata sa slike i izračunavanje momenata sjaja i još jedan ključan parametar za separaciju zvezda i galaksija (FWHM), korišćen je program Sextractor v2.8.6 (Bertin & Arnouts, 1996).¹ Ovaj program pravi katalog objekata sa slike, uz numeraciju i izračunavanje različitih parametara za svaki od objekata (koordinate, FWHM, izofotalne i aperturne magnitude itd.), koristeći analizu površinskog sjaja objekta na slici. Program Sextractor zahteva izvesno podešavanje parametara kako bi zavisno od veličine objekata i nivoa šuma uspešno izvršio separaciju objekata, bez njihovog međusobnog preklapanja ili "rasparčavanja" složenih struktura, kao što su bliske galaksije. S obzirom na to da se crveni pomak menja u značajnom opsegu imajući u vidu izgled galaksija ($0.003 < z < 0.06$), promenjeni su parametri koji se odnose na nivo jačine signala iznad šuma, koji je potrebno dostići da se pojava na slici smatra objektom (DETECT_MINAREA = 3) i da se dalje analizira (DETECT_THRESH = ANALYSIS_THRESH = 3). SNR je fiksiran na 3σ za ceo α -uzorak, jer se na ovaj način detektuju samo sjajni objekti na slici. Parametar DEBLEND_MINCONT na osnovu prostorne raspodele fluksa objekata odlučuje, zavisno od mere njihovog uzajamnog preklapanja imamo li različite objekte ili različite delove jednog istog objekta i fiksiran je na vrednost 0.1 (slika 5.1). Ovo je najznačajniji korak u kreiranju kataloga. Parametar DEBLEND_MINCONT "odlučuje" koji pikseli pripadaju kom objektu. Može se shvatiti kroz ilustraciju brdovitog predela. U osnovi imamo uzvišenje i to bi mogla biti jedna galaksija. Kako idemo "naviše" pojavljuju se brda koja mogu biti druge galaksije ili zvezde naše Galaksije, ali i delovi jedne iste galaksije (slika 5.1). Pomoću ovog parametra mi *unapred* sugerišemo programu da li želimo da imamo jednu galaksiju ili očekujemo kontaminaciju drugim objektima. Kako su sve galaksije α -uzorka bliske, potrebno je podesiti "prag" pripajanja piksela jednom objektu, kako bi se izbeglo "rasparčavanje"

¹<http://www.astromatic.net/software/sextractor>

Slika 5.1: Razdvajanje objekata iz priručnika za SExtractor prikazano strukturom drveta: razdvojena su dva objekta A i B, dok će preostali pikseli biti dodeljeni jednom od njih, ali smanjenjem parametra DEBLEND_MINCONT, idemo naviše, te možemo izdvojiti čak četiri objekta. Za bliske galaksije parametar treba učiniti većim, kako se galaksija ne bi "raspala" na sastavne delove.

galaksije na sopstvene delove. Istovremeno se pravi tzv. maska objekata. Maska je slika objekata koji odgovaraju svojoj površini na originalnoj slici, ali im je intenzitet izražen celim brojem koji odgovara njihovoj numeraciji u katalogu. Na slici 5.2 (gore) prikazana je originalna SDSS slika galaksije Alfalfa 200336 i njena odgovarajuća maska kreirana pomoću SExtractor-a. Potrebna je samo jedna intervencija na slici, naime objekat modelovanja mora imati piksele maske jednake nuli. Na ovaj način se pravi slika dobrih piksela (dobar piksel = 0, loš piksel \neq 0). I upravo iz ovog razloga na slici 5.2 dole (maska) nedostaje galaksija, a zapravo su njeni pikseli izjednačeni sa nulom, kao i pozadinski.

Slika 5.2: Gore: Originalna SDSS slika galaksije Alfa 200336. Dole: Maska slike gde je intenzitet svakog objekta jednak njegovom broju u katalogu. Jedino nedostaje galaksija kojoj su dodeljeni pikseli jednaki nuli, kao i pozadini, te se stoga ne vidi na donjoj slici.

Još jednom treba napomenuti da kao rezultat dobijamo ceo katalog numerisan kao na masci, sa različitim parametrima izračunatim za svaki dati objekat. U ovoj tezi, korišćeni su sledeći parametri: koordinate u pikselima (X_IMAGE, Y_IMAGE) ili prvi momenti intenziteta radi pozicioniranja objekata na slici, svetske koordinate (X_WORLD, Y_WORLD) u EqJ2000 sistemu, izofotalna magnituda (MAG_ISO), koordinate rama oko objekta sa merljivim intenzitetom (X_MIN, X_MAX, Y_MIN, Y_MAX) ili najveća površina koju zauzima objekat, velika i mala poluosu (A_IMAGE, B_IMAGE), pozicioni ugao (THETA_IMAGE), FWHM Gausijana centriranog na objekat (FWHM_IMAGE) i radijus kruga koji zahvata polovinu intenziteta (FLUX_RADIUS). Slika 5.3 ilustruje upotrebu nekih od pomenutih parametara značajnih za analizu² :

$$\begin{aligned}
CXX_IMAGE &= \frac{\cos^2(THETA_IMAGE)}{A_IMAGE^2} + \frac{\sin^2(THETA_IMAGE)}{B_IMAGE^2}, \\
CYY_IMAGE &= \frac{\sin^2(THETA_IMAGE)}{A_IMAGE^2} + \frac{\cos^2(THETA_IMAGE)}{B_IMAGE^2}, \\
CXY_IMAGE &= 2 \cos(THETA_IMAGE) \sin(THETA_IMAGE) \times \\
&\quad \left(\frac{1}{A_IMAGE^2} - \frac{1}{B_IMAGE^2} \right).
\end{aligned} \tag{5.1.1}$$

Ovo je jednačina izofotalne elipse (slika 5.3), unutar koje se izračunava izofotalna magnituda (MAG_ISO). Izofota, odnosno elipsa je zadata na granici detekcije objekta.

Svi ovi izračunati parametri predstavljaju ulazne (inicijalne) parametre za IRAF-ovu³ **ellipse** proceduru koja sa zadatim korakom traži konture istog sjaja (izofote) do nultog intenziteta. U ovoj tezi, fotometrija α -uzorka je preuzeta iz SDSS DR8 baze slika, pošto su počev od DR8 slike dostupne bez pozadine. Oduzimanje pozadine je kompleksan problem, koji nije zadovoljavajuće rešen ni u jednom od korišćenih programa. Krajnji rezultat je profil površinskog sjaja galaksije, koji dalje služi za podešavanje inicijalnih

²<https://www.astromatic.net/pubsvn/software/sextractor/trunk/doc/sextractor.pdf>.

³IRAF je skup programa namenjenih astronomskoj zajednici, razvijanih tokom 30 godina sa ciljem obrade i analize spektroskopskih i fotometrijskih podataka: <http://iraf.net>.

Slika 5.3: Izofotalna elipsa radijusa $R = 3$ sa parametrima CXX , CYY i CXY koji se mogu izračunati iz drugog momenta sjaja (jednačina 5.1).⁵

parametara za dekompoziciju. Dekompozicija je urađena pomoću programa Galfit. Ovaj program modeluje površinski sjaj astronomskih objekata određenim brojem analitičkih funkcija, koje dobro opisuju različite astronomske objekte (zvezde, galaksije i posebno delove galaksija). Tako su na raspolaganju sledeće analitičke funkcije: Sersikov, Devokuleroov i eksponencijalni zakon, Mofatova, Fererova i Gausova funkcija i mnoge druge. U ovoj tezi program je korišćen za modelovanje površinskog sjaja galaksija. Primenom nelinearne metode najmanjih kvadrata, u prostoru zadatih inicijalnih parametara Galfit iterativno traži najbolje rešenje u smislu χ^2 statistike, kreirajući model galaksije. Program traži i PSF funkciju, kako bi model galaksije zadat nekom analitičkom funkcijom konvoluirao sa PSF funkcijom i oduzimanjem od originalne slike galaksije proizveo rezidualne. PSF funkcija je određena IRAF-ovom `psf` procedurom automatski, tako što se iz FWHM svih objekata identifikuju zvezde uslovom da je za zvezdu magnitude mag_* i širine na polovini maksimuma $FWHM_*$:

$$\begin{aligned} mag_* &< \overline{mag} - 1/4 \sigma \\ 2 \times \text{median}(FWHM) + 1 &> FWHM_* > 2 \times \text{FLUX_RADIUS}. \end{aligned} \quad (5.1.2)$$

Srednja izofotalna magnituda $\overline{\text{mag}}$ i medijana FWHM $\text{median}(\text{FWHM})$ iz jednačine 5.1.2, izračunate su koristeći vrednosti magnituda i FWHM svih objekata na slici, izmerenih programom Sextractor. FLUX_RADIUS je parametar izmeren istim programom i predstavlja radius unutar kojeg je sadržana polovina ukupnog fluksa objekta. Jednačina 5.1.2 je empirijski uslov, koji se nakon dužeg testiranja pokazao uspešnim u razdvajanju zvezda i drugih objekata na slici i služi za kreiranje liste zvezda, radi izračunavanja PSF funkcije. Još je potrebno odbaciti sve one zvezde koje imaju u blizini druge objekte i konačno se njihova lista sortira po sjaju, tako da se za pravljenje PSF funkcije uzima najmanje 5, a najviše 50 sjajnih, izolovanih zvezda. IRAF-ova `psf` procedura poziva se sa sledećim parametrima: $\text{FWHM} = \text{median}(\text{FWHM})$ i uslovom da radius unutar kojeg se profil zvezda fituje Mofatovom funkcijom eksponenta 1.5 iznosi $3.5 \times \text{median}(\text{FWHM})$. Na slici 5.4, prikazana je: 1) PSF funkcija galaksije sa slike 5.2, 2) slika kontura istog sjaja, 3) njen radijalni profil i 4) prostorna raspodela. Značajno je primeti na slici radijalnog profila (slika 5.4) da i u krillu funkcija glatko prati tačke, što znači da je model koji opisuje PSF funkciju dobar i da je dovoljno visok SNR (odnosno da su zvezde korišćene za kreiranje PSF funkcije sjajne).

Galfit još zahteva tzv. σ -sliku, odnosno mapu neodređenosti fluksa u svakom pikselu. Da bi rezultat bio značajan u statističkom smislu (χ^2 statistike), svaka tačka (piksel) mora imati odgovarajuću težinu, jer pikseli koji sadrže jači signal su pouzdaniji od onih sa slabijim signalom.⁴ σ - slika sadrži i zbirnu informaciju o postupcima obrade slike⁵ i u opštem slučaju (i najjednostavnijem) može se izračunati sledećom formulom:

$$\sigma = \frac{\sqrt{(\text{ADU} \times \text{GAIN} \times \text{NCOMBINE})^2 + (\text{RMS} \times \sqrt{\text{NCOMBINE}})^2}}{\text{GAIN}}, \quad (5.1.3)$$

⁴Ovo se naravno odnosi na analizirani objekat, a ne na okolne objekte koji mogu biti i sjajniji i koje smo prethodno uspešno odstranili pomoću adekvatne maske.

⁵Na primer, da li je više slika usrednjeno ili sabrano i da li su neki skalirajući faktori primenjeni prilikom obrade slike.

gde je ADU intenzitet fluksa u svakom pikselu, GAIN je faktor pojačanja struje, NCOMBINE broj usrednjenih slika, a RMS intenzitet neba (pozadina).

(1)

(2)

(3)

(4)

Slika 5.4: PSF funkcija galaksije sa slike 5.2, gde je: (1) slika PSF, (2) konture istog sjaja (izofote), (3) radijalni profil fitovan funkcijom Moffat15 i (4) prostorna raspodela fluksa PSF funkcije. Radi bolje preglednosti slike su date bez osa, ali je svuda u pitanju zavisnost intenziteta od radijusa.

Množenjem $\text{ADU} \times \text{GAIN}$ slika se iz ADU pretvara u elektrone, jer Poasonova statistika

važi za elektrone i omogućava da se u kvadraturi doda intenzitet neba (RMS). Na kraju se deli sa GAIN parametrom da se ponovo vrati u ADU. Ova formula je validna ukoliko slikom dominira pozadina, jer je izvedena uz pretpostavku da nebo dominira regionom koji se fituje. U suprotnom, ako je objekat dominantan, σ -slika se ne može računati na ovaj način. Naravno, najbolje je unapred napraviti σ -sliku i u slučaju SDSS DR8 galaksija, kreiranje σ -slike je dobro dokumentovano.⁶ Na slici 5.5 prikazana je σ -slika galaksije sa slike 5.2. Razlika je jedva uočljiva golim okom, pošto je σ -slika grubo $\sqrt{\text{fluks}}$. σ -slika koristi se direktno za izračunavanje χ^2 , odnosno zbira odstupanja fluksa sa slike i modela u odnosu na očekivana odstupanja (σ):

$$\chi^2 = \frac{1}{N_{\text{dof}}} \sum_{x=1}^{nx} \sum_{y=1}^{ny} \frac{(f_{\text{galaksija}}(x, y) - f_{\text{model}}(x, y))^2}{\sigma(x, y)}, \quad (5.1.4)$$

gde je $f_{\text{galaksija}}(x, y)$ fluks galaksije u svakom pikselu (x,y), f_{model} analitički model koji Galfit generiše u svakom pikselu (x,y), N_{dof} broj stepeni slobode ($N_{\text{dof}} \sim nx \times ny$), a $\sigma(x, y)$ je Poasonovo (Gausovo) odstupanje fluksa u svakoj tački slike. Pa ipak, čak i uz valjanu σ -sliku, χ^2 nije merilo uspešnosti fita,⁷ jer je na izvestan način narušena χ^2 statistika. Naime, reziduali nisu samo Poasonov šum, već mogu oslikavati strukture koje nismo ili ne možemo fitovati, PSF funkcija nije savršena itd. Ali uzajaman odnos χ^2 različitih modela, govori mnogo o uspešnosti tih modela u relativnom smislu, jednih u odnosu na druge. I tako se na osnovu χ^2 , koji ne mora i često neće biti ≤ 1 , može odabrati najbolji model.

5.2 Dekompozicija radijalnih profila sjaja galaksije

Potrebni ulazni parametri u Galfit program, opisani u prethodnom poglavlju su: slika galaksije, σ -slika, maska i PSF funkcija. Galfit u osnovi koristi nelinearnu metodu naj-

⁶http://data.sdss3.org/datamodel/files/BOSS_PHOTOOBJ/frames/RERUN/RUN/CAMCOL/frame.html

⁷<https://users.obs.carnegiescience.edu/peng/work/galfit/CHI2.html>

Slika 5.5: Sigma slika galaksije sa slike 5.2.

manjih kvadrata i rešenje traži iterativno. Zato je jako važno podesiti početne parametre tako da se ne dozvole velika odstupanja za koja se ne može naći rešenje ili za koja se pronalazi lokalni minimum, koji nije ujedno i globalni minimum. Kako bi se proces automatizovao, početni parametri se mogu odrediti iz linearnog fita jednostavnih analitičkih funkcija koje opisuju galaksije (Devokulov i eksponencijalni profil). Neznatno je složenija situacija sa Sersikovim profilom, pošto se u linearnoj metodi eksponent ne može varirati, ali se za fiksirane vrednosti indeksa u nekom intervalu prema najmanjem χ^2 fita može odabrati indeks. Ovaj indeks je samo početna vrednost Sersikovog indeksa, koju će Galfit koristiti. Situacija se komplikuje ukoliko želimo da opišemo galaksiju pomoću dve komponente, ali predznanje o tome da imamo oval i disk je umnogome pojednostavljuje. Recept uspešnog dvokomponentnog modelovanja jeste da se obe komponente opišu svojim jednokomponentnim pandanima do (od) nekog radijusa, samo sa umanjenim sjajem, pošto u svakoj tački umesto jedne komponente imamo zbir dve. Dovoljno je magnitude uvećati za jednu veličinu, a radijus *do* kojeg fitujemo centralni oval i *od* kojeg fitujemo disk proglasimo velikom poluosom galaksije, koju izračunava SExtractor. Na ovaj način, čak i dvokomponentno fitovanje se može izvršiti bez ikakve intervencije. Na slikama 5.6 prikazani su jednokomponentni i dvokomponentni fitovi (sa

uvećanim magnitudama), iz kojih se dobijaju početni parametri za Galfit. Ovi fitovi nisu dobri u smislu χ^2 statistike, ali su dovoljno dobri za inicijalizaciju parametara koji su potrebni Galfitu. Cilj podešavanja početnih parametara nije traženje najboljeg modela koji datu galaksiju opisuje, već samo kreiranje inicijalnih modela koji se zatim predaju Galfitu, kako bi variranjem datih parametara uspešno minimizovao χ^2 koristeći celu sliku, odnosno dvodimenzionalnu informaciju. Suština je da se početni parametri podese tako da ne budu suviše različiti od svojih "pravih" vrednosti, inače Galfit neće uspeti da nađe globalni minimum. Formule pomoću kojih se iz linearnih funkcija određuju inicijalni parametri u slučaju Sersikovog profila su:

$$\mu_{\text{eff}} = \text{odsečak} - 2.5(2n - 0.327)/\ln(10), \quad \text{i} \quad (5.2.1)$$

$$r_{\text{eff}} = \left(\frac{2.5 * (2n - 0.327)/\ln(10)}{|\text{nagib}|} \right)^n. \quad (5.2.2)$$

Analogno se dobijaju efektivni površinski sjaj i radijus i za ostale profile, samo je za Devokulerov profil $n = 4$, a za eksponencijalni disk $n = 1$. Važno je napomenuti da Galfit ima veliki broj slobodnih parametara (za svaki profil: koordinate centra, sjaj, radijus, eliptičnost i pozicioni ugao), te je stoga potrebno fiksirati neke parametre, inače se mogu dobiti besmisleni rezultati. Na primer, od značaja je fiksiranje koordinata centra galaksije obe komponente, na taj način da se zajedno variraju, ali da se ne dozvoli programu da centar diska pomeri u odnosu na centar ovala. Ovo se postiže pravljenjem fajla `constraints`, gde se naznači:

```
# Component/ parameter constraint Comment
1_2 x offset
1_2 y offset
2/1 re 1 10
```

Drugim rečima, u slučaju modelovanja dve komponente neka x koordinata druge komponente prati prvu, i isto se odnosi i na y koordinatu (značenje izraza 1_2). Poslednji red govori Galfitu da je efektivni radijus diska veći od efektivnog radijusa ovala od 1 do

Slika 5.6: Linearni fitovi analitičkih funkcija profila površinskog sjaja galaksije (prazni kružići) sa slike 5.2. Levo: jednokomponentni fitovi i to Devokulov (tačkasta linija), eksponencijalni (puna linija) i Sersikov sa $n = 1$ (isprekidana linija). Desno: dvokomponentni fitovi i to Devokulov oval sa eksponencijalnim diskom (crvena linija), eksponencijalni oval sa eksponencijalnim diskom (plava linija) i Sersikov centralni oval sa eksponencijalnim diskom (zelena linija).

10 puta, kako bi se izbeglo fitovanje nuklearne komponente eksponencijalnim profilom. Ovaj fajl, zajedno sa inicijalnim parametrima predaje se programu Galfit u specijalnom fajlu ekstenzije `feedme`, čiji je primer za slučaj dve komponente (Sersikov centralni oval i eksponencijalni disk) dat u dodatnom materijalu (G).

Na slici 5.7 prikazan je `fits` fajl, koji se dobija pomoću programa Galfit. Ovaj fajl se sastoji od tri slike (odozgo na dole): originalne slike galaksije, slike najboljeg modela unapred zadate analitičke funkcije i slike reziduala fita, koja se dobijaju oduzimanjem reziduala od modela galaksije konvoluiranog sa PSF funkcijom. Primer je prikazan za

galaksiju Alfalfa 200366. Zadana analitička funkcija je Sersikov centralni oval sa eksponencijalnim diskom i ujedno je i najbolji model u smislu χ^2 statistike ($\chi^2 = 1.03$).

Najoptimalnije rešenje pri fitovanju dve komponente od koje je jedna eksponencijalna funkcija kojom se želi opisati disk, jeste da se odnos male i velike poluose i pozicioni ugao drže fiksirani na vrednosti iz jednokomponentnog fita Sersikovom funkcijom. Ovo je ujedno i najstabilnije rešenje i sprečava kod da se zaustavi i najbolje pošto u ovom slučaju znamo da se disk glaksije najbolje opisuje eksponencijalnom funkcijom. Konačno, rezultati su radi bolje vizuelizacije prikazani kao analitičke funkcije u jednoj dimenziji preko tačaka profila površinskog sjaja dobijenih IRAF-ovom `ellipse` procedurom uz azimutalno usrednjavanje (slika 5.8). Podjednako su dobri Ser + Exp i Exp + Exp dvokomponentni modeli, koji imaju $\chi^2 = 1.03$ (puna zelena i plava linija). Najlošiji model je Devokulerov oval sa eksponencijalnim diskom (Dev + Exp: puna crvena linija) sa $\chi^2 = 1.08$.

Svi mereni parametri dati su u tabelama: H.1 i H.2 u Dodatku H za Devokulerov, eksponencijalni i Sersikov jednokomponenti profil. Kod neuspešnih modela (onih koji su doveli do kraha programa Galfit), svi parametri izjednačeni su sa -9999. U narednom potpoglavlju, oni će biti upoređeni sa postojećim rezultatima.

Slika 5.7: Izlaz iz Galfit programa, odozgo na dole: originalna slika, model i reziduali fita. Primer se odnosi na galaksiju Alfalfa 200336. Galaksija je modelovana dvokomponentnim modelom: Sersikovim centralnim ovalom i eksponencijalnim diskom.

Slika 5.8: Rezultati programa Galfit za galaksiju Alfalfa 200336 prikazani u vidu analitičkih funkcija radi bolje vizuelizacije preko tačaka profila površinskog sjaja u jednoj dimenziji (prazni kružići). Fitovane funkcije: jednokomponentne su prikazane isprekidanim linijama (Sersikov: Ser, Devokulerov: Dev i eksponencijalni: Exp profil), a dvokomponentne punim linijama (Sersikov pseudo oval i eksponencijalni disk: Ser + Exp, Devokulerov pseudo oval i eksponencijalni disk: Dev + Exp i eksponencijalni oval sa eksponencijalnim diskom: Exp + Exp).

5.3 Poređenje sa postojećim rezultatima

Rezultati modelovanja površinskog sjaja galaksija iz α -uzorak, baziranog na fotometriji iz SDSS DR8 baze podataka, upoređeni su sa postojećim rezultatima. Postoje dve velike baze dekompozicije SDSS slika. Obe su zasnovane na rutinama, koje su potpuno automatizovane, s obzirom na to da rade sa blizu milion galaksija. To su: 1) SDSS rutine koje izračunavaju jednokomponentni eksponencijalni i Devokulerov profil i 2) uPenn katalog (Meert et al., 2016), koji pored jednokomponentnih Sersikovih i Devokulerovih profila, daje i dvokomponentne: Devokulerov oval sa eksponencijalnim diskom i Sersikov centralni oval sa eksponencijalnim diskom.

uPenn katalog je zasnovan na fotometriji iz baze SDSS DR7, dobijen sličnim pristupom. Naime, korišćen je Sextractor za kreiranje maske i Galfit za finalnu dekompoziciju. PSF slike su preuzete iz tzv. `PsField` fajlova. σ -slika je kreirana na osnovu dostupnih informacija koristeći standardnu formulu za SDSS DR7:

$$W_{i,j} = \sqrt{\frac{F_{i,j}}{\text{GAIN}} + \text{DARK VARIANCE}}, \quad (5.3.1)$$

gde je $W_{i,j}$ neodređenost fluksa u svakom pikselu (i, j) , $F_{i,j}$ fluks u svakom pikselu, GAIN faktor pojačanja struje, a DARK VARIANCE struja grejanja CCD detektora.

uPenn katalog sadrži 2014 zajedničkih galaksija, pa samim tim poređenje sadrži umanjen broj galaksija. Takođe, oba rada koriste σ -sliku, što χ^2 statistiku čini korisnom za međusobno poređenje, ali i eliminaciju rezultata. Sve dekompozicije sa $\chi^2 > 1.3$ su zanemarene, pošto su takvi modeli neadekvatni i otežavaju poređenje.

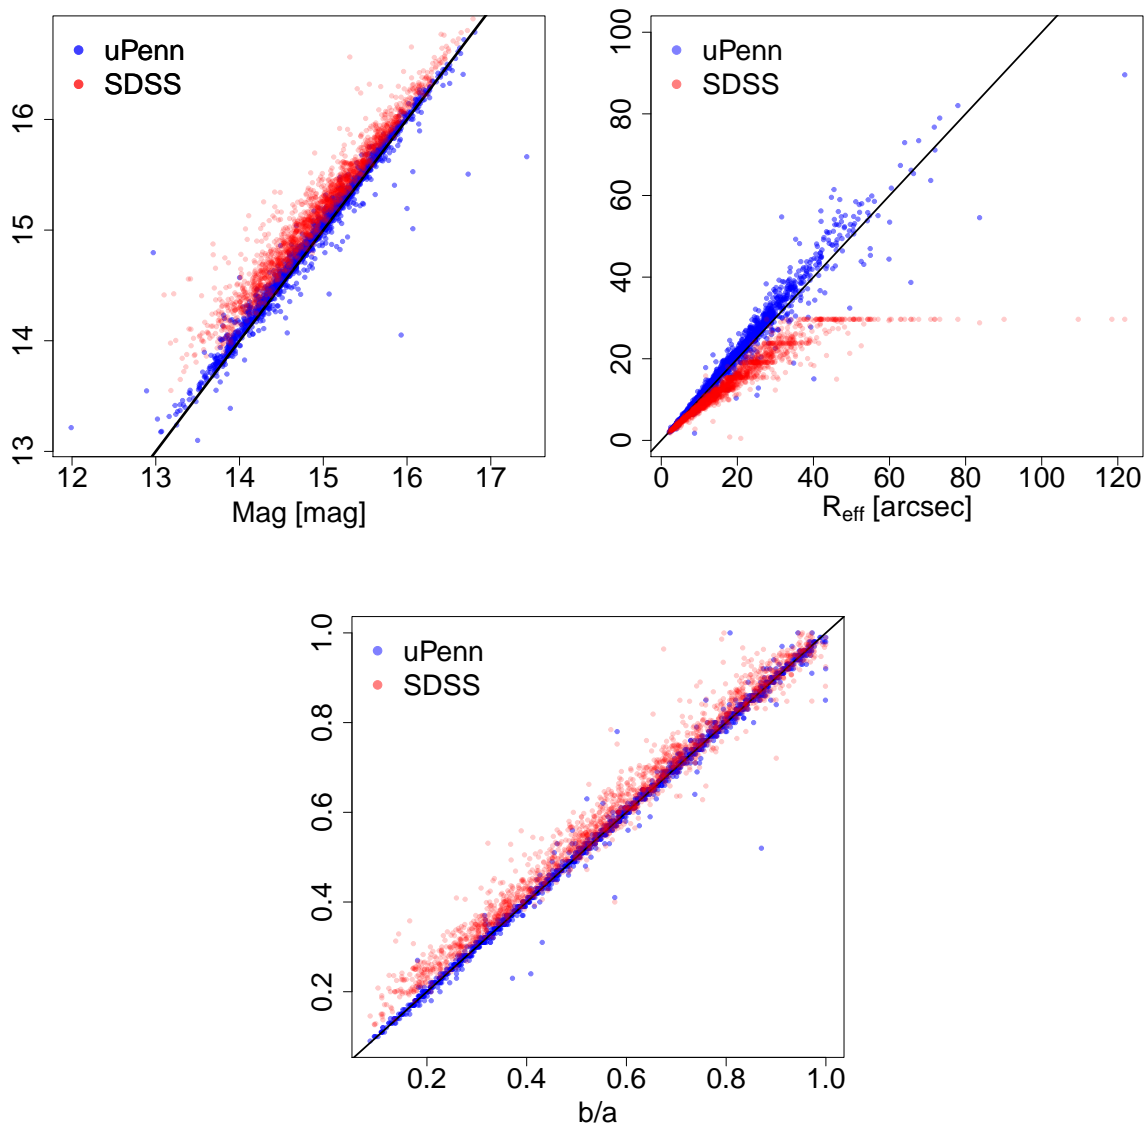

SDSS rutine zanemaruju sjaj galaksije dalje od 7 efektivnih radijusa, tako što ga glatko dovode na nulu izvan 8 efektivnih radijusa i ovaj "omekšivač" menja vrednost ukupne magnitude. U bazi CasJobs nađeno je 2170 objekata u tabeli `PhotoObjAll` zajedničkih sa α -uzorkom.

Od posebnog značaja za ovaj rad je Sersikov indeks, koji opisuje stepen koncentracije sjaja galaksije i može poslužiti i za grubu morfološku klasifikaciju. Uzima učešće i u

izračunavanju dinamičke mase galaksija. Takođe, u slučaju dvokomponentne dekompozicije, stepen centralnog ovala razlikuje klasičan oval od pseudoovala.

Poređenje sa oba kataloga moguće je samo u slučaju Devokuleroovog profila, pošto SDSS rutine ne izračunavaju Sersikov profil i ostaju na jednodimenzionalnom modelovanju. Na slici 5.9 dato je poređenje oba kataloga u slučaju jednokomponentnog Devokuleroovog profila. Slaganje magnituda sa uPenn katalogom je izvrsno (slika 5.9), dok se sistematsko odstupanje u slučaju SDSS magnitude može objasniti "omekšavanjem" profila sjaja, kao što je već pomenuto. Sa druge strane, efektivni radijusi slažu se sa uPenn katalogom u okviru grešaka fita koje iznose oko 1%. Na slici 5.9 (dole) je dato poređenje b/a , čije je odstupanje zanemarljivo u slučaju uPenn kataloga. Rezultati SDSS-a su problematični, jer izgleda da postoji nekakva maksimalna vrednost za efektivni radijus iznad koje nema rezultata. Ispod ove granice, efektivni radijus je potcenjen. Odnos male i velike poluose b/a se jako dobro slaže u oba slučaja.

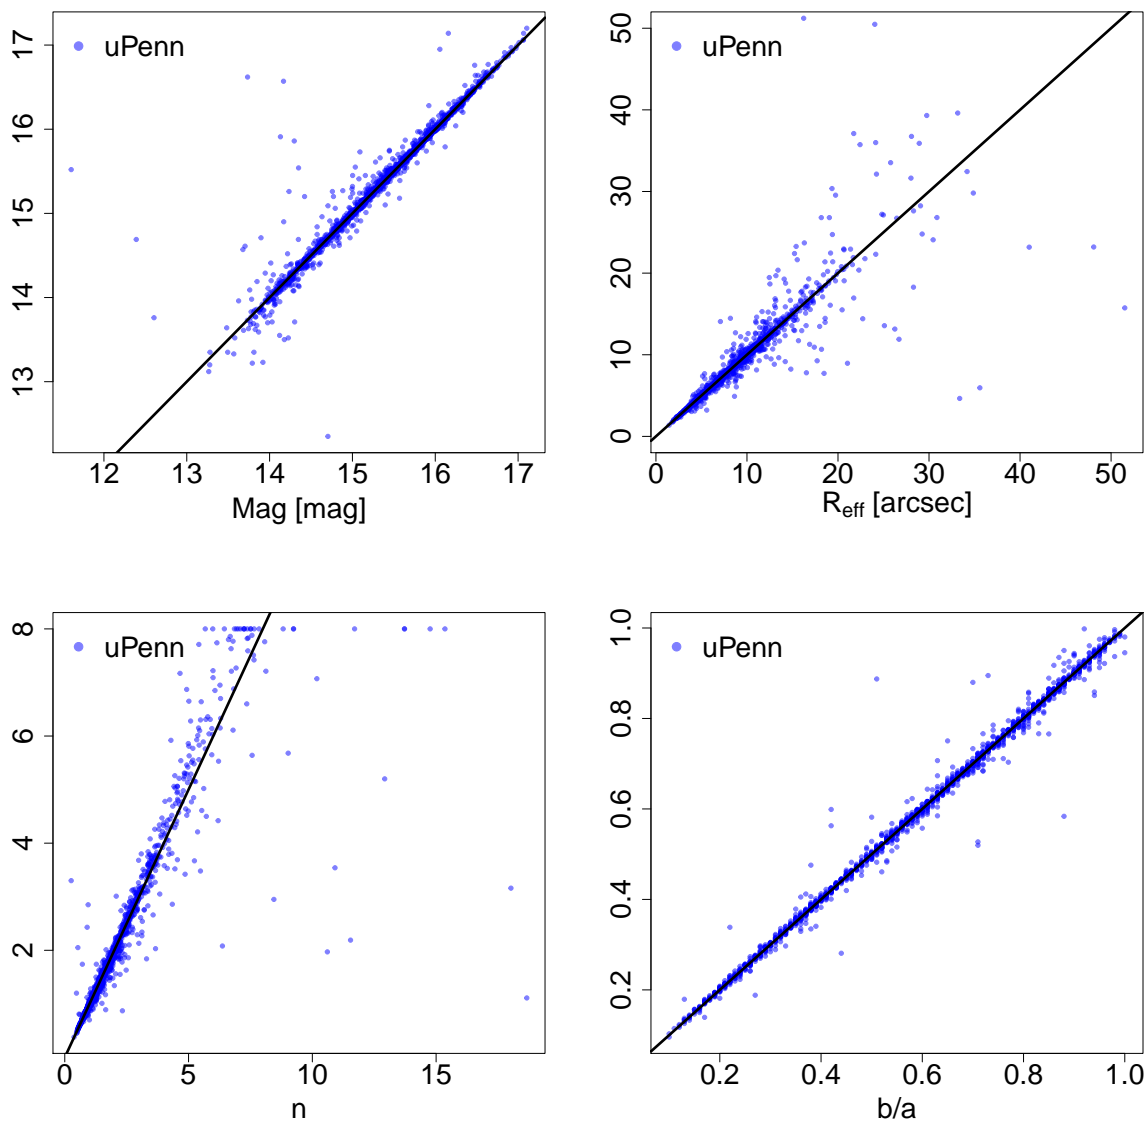

Konačno, poređenje Sersikovog indeksa u slučaju jednokomponentnog modela dato je na slici 5.10. Slaganje je i dalje dobro, ali ako se uporedi sa slaganjem za Devokuleroov profil (slika 5.9), rasipanje je primetno i posledica jednog dodatnog parametra fita – Sersikovog eksponenta koji je bio $n = 4$ za Devokuleroov profil (fiksiran), a sada se menja neograničeno. Upravo iz ovog razloga, kod dvokomponentnog modelovanja, dva parametra su fiksirana: odnos male i velike poluose (b/a) i pozicioni ugao (PA) na vrednosti najboljeg jednokomponentnog Sersikovog fita. Na ovaj način disk ne može da pretrpi veće perturbacije, čak i ako neki okolni objekti nisu dobro maskirani. Takođe, smanjuje se broj slobodnih parametara i dobijaju se stabilnija rešenja (u smislu malog variranja parametara oko početnih vrednosti). Kao što je ranije pomenuto, nametnuto je inicijalno rešenje da je radijus diska veći od radijusa ovala i zajedničke koordinate obe komponente. Sva navedena ograničenja dovode do značajnog odstupanja poređenih parametara (slika 5.11) sa uPenn katalogom, gde su svi parametri slobodni. Za odstupanja je delom odgovorna i različita obrada slika u SDSS DR7 i SDSS DR8 publikacijama. Jedan od

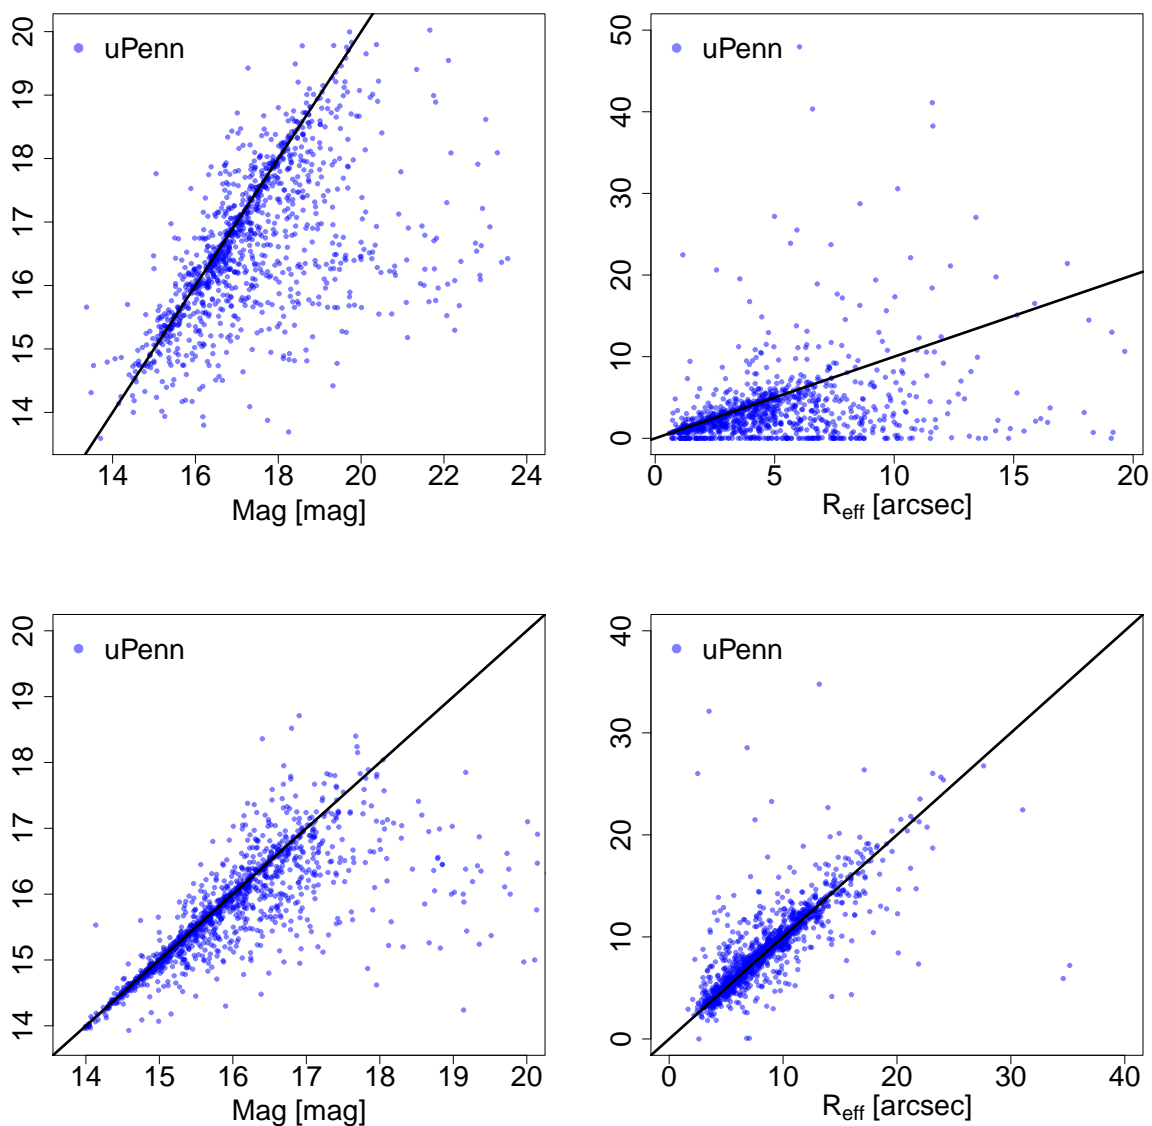

Slika 5.9: Poređenje dobijene ukupne magnitude (gore levo), efektivnog radijusa (gore desno) i odnosa male i velike poluose (dole) sa rezultatima SDSS (crvene tačke) i uPenn kataloga (plave tačke) za jednokomponentni Devokulerov profil. Svuda su oznake na x - i y -osi iste, i stoga su date samo na x -osi, koja se odnosi na merene veličine u ovoj tezi. Puna linija je funkcija $y = x$.

najznačajnijih faktora je drugačije tretiranje pozadine, koja je presudna za modelovanje programom Galfit. Od manjeg značaja je σ -slika, koja je takođe različita. Uzimajući sve u obzir, slaganje je zadovoljavajuće. Rezultati dvokomponentnog modelovanja dati su u tabelama: H.3, H.4 i H.5 u Dodatku H i to redom za Devokulero centralni oval sa eksponencijalnim diskom, eksponencijalni centralni oval sa eksponencijalnim diskom i Sersikov centralni oval sa eksponencijalnim diskom. Kao i u slučaju jednokomponentnih modela, parametrima neuspešnih modela pridodata je vrednost -9999. Parametri diska: b/a i PA dati su bez grešaka, pošto su fiksirani tokom fita. Ostali parametri se menjaju u skladu sa ograničenjima nametnutim u fajlu `constraints`.

Modelovanje površinskog sjaja galaksija urađeno je sa ciljem dobijanja parametara za statističku analizu: Sersikvog indeksa i efektivnog radijusa jednokomponentnog Sersikvog modela. Ovi parametri će biti korišćeni u šestom poglavlju za izračunavanje dinamičke mase, zajedno sa disperzijom brzina, izračunatom u trećem poglavlju. U analizi ćemo koristiti još i Likove indekse $\langle Fe \rangle'$ i H_{β} , kao indikatore metaličnosti i starosti, izračunate u četvrtom poglavlju. U prethodnim poglavljima, dakle, izmereni su parametri, koji će upotpuniti prostor parametara za statističku analizu.

Slika 5.10: Poređenje dobijene ukupne magnitude (gore levo), efektivnog radijusa (gore desno), Sersikovog indeksa (dole levo) i odnosa male i velike poluose galaksije (dole desno) sa rezultatima iz uPenn kataloga za jednokomponentni Sersikov profil. Svuda su oznake na x - i y -osi iste, i stoga su date samo na x -osi, koja se odnosi na merene veličine u ovoj tezi. Puna linija odgovara funkciji $y = x$.

Slika 5.11: Poređenje dobijene ukupne magnituda i efektivnog radijusa za centralni oval (gore) i disk (dole) sa rezultatima iz uPenn kataloga za dvokomponentni Sersikov profil. Svuda su oznake na x - i y -osi iste, i stoga su date samo na x -osi, koja se odnosi na merene veličine u ovoj tezi. Puna linija odgovara funkciji $y = x$.

Poglavlje 6

Metoda osnovnih komponentata

Metoda osnovnih komponentata je statistička metoda svođenja višedimenzionalnog prostora parametara na najmanji broj dimenzija dovoljan da ih opiše. U ovoj tezi biće primenjena na odgovarajući skup parametara, koji opisuju fundamentalne osobine galaksija sa ciljem pronalaženja i identifikacije najmanjeg broja dimenzija, koje čine ovaj prostor. Osnovne komponente u ovoj tezi izračunate su pomoću procedure `princomp` programskog jezika R¹.

U ovom poglavlju biće analiziran širi skup parametara: Petrosijanovi radijusi koji obuhvataju 50% i 90% ukupnog fluksa (R_{50} i R_{90}), dinamička masa (M_{dyn}), masa gasne komponente (M_{HI}), zvezdana masa (M_k), Likovi indeksi ($\langle \text{Fe} \rangle'$ i H_β), boje ($g - r$ i $NUV - r$), disperzija brzina (σ), luminoznost u g filteru (L_g), maksimalna rotaciona brzina (V_r) i masa tamnog haloa ($\log M_{\text{DM}}$).

Poglavlje je koncipirano na sledeći način: u potpoglavlju 6.1 predstavljen je skup parametara značajnih za ovu analizu i neophodne korekcije istih; u potpoglavlju 6.2 predstavljeno je određivanje mase različitih komponentata galaksije; u potpoglavlju 6.3 primenjena je korelaciona analiza kako bi se ispitala veze (korelacije) među parametrima koji su zatim korišćeni u analizi osnovnih komponentata.

¹R je programski jezik namenjen prevashodno statističkoj analizi: <https://www.r-project.org>.

6.1 Fotometrijske korekcije

Nadalje će biće korišćene magnitude od ultraljubičastog do bliskog infracrvenog dela spektra. Ovo su prividne magnitude i podložne su ekstinkciji i kosmološkiim efektima. Ovi efekti - posledica prisustva prašine i širenja Univerzuma - dodaju se prividnoj magnitudi kao korekcije

$$m - M = 5 \log D[\text{Mpc}] + 25 + k(z) + A_\lambda, \quad (6.1.1)$$

gde je $k(z)$ K-korekcija, a A_λ umanjenje sjaja objekta zbog Galaktičke ekstinkcije. Korrigovana magnituda m^0 zadovoljava:

$$m^0 - M = 5 \log D[\text{Mpc}] + 25. \quad (6.1.2)$$

Galaktička ekstinkcija je umanjenje sjaja objekta, zbog prolaska svetlosti kroz našu Galaksiju, odnosno kroz čestice prašine koje apsorbuju i rasejavaju svetlost izvora. Zavisi isključivo od pozicije objekta i talasne dužine, pošto se kraći talasi više rasejavaju od dužih. Ekstinkcija uzrokovana prašinom prati zakon ekstinkcije (Cardelli et al., 1989) i može se izraziti pomoću samo jednog parametra – vidljive ekstinkcije A_V . Kako bi se dobila ekstinkcija za izvestan opseg talasnih dužina, potrebno je izvršiti integraciju koristeći "odgovor filtera" (engl. filter response curve). Mape prašine (Schlegel et al., 1998), koriste se za računanje ekstinkcije duž date vizure. Linijska gustina prašine kalibrisana je tako da daje pocrvenjenje $E(B - V)$ za svaku datu vizuru. Kako gustina međuzvezdane materije varira duž neba, menja se i ekstinkcija. Iznos ekstinkcije može se kvantifikovati izrazom:

$$R_V \equiv \frac{A_V}{E(B - V)}, \quad (6.1.3)$$

gde je R_V odnos ukupne prema selektivnoj ekstinkciji. Tipična vrednost $R_V = 3.1$, ali može iznositi i ~ 5 , u gušćim regionima. Cardelli et al. (1989) našli su empirijski zakon ekstinkcije:

$$\left\langle \frac{A_\lambda}{A_V} \right\rangle = a(x) + \frac{b(x)}{R_V}, \quad (6.1.4)$$

gde je $x = 1/\lambda$, a $a(x)$ i $b(x)$ stepene funkcije. Zakon je dat za jednu vrednost talasne dužine. U slučaju širokopojasnog filtera, potrebno je primeniti određene korekcije.

Za GALEX magnitude, Peek & Schiminovich (2013) daju:

$$A_{FUV} = E(B - V)[10.47 + 8.59 E(B - V) - 82.8 E(B - V)^2] \quad (6.1.5)$$

$$A_{NUV} = E(B - V)[8.36 + 14.3 E(B - V) - 82.8 E(B - V)^2]. \quad (6.1.6)$$

Vrednosti $E(B - V)$ date su u tabeli PhotoObjA11 za GALEX GR6.² Za SDSS (u, g, r, i, z) magnitude, pocrvenjenje je dato za svaki posmatrani objekat u tabeli PhotoPrimaryDR7³. Za 2MASS magnitude (J, H, K_s), Yuan et al. (2013) daju izraze: $R_J = 0.72$, $R_H = 0.46$ i $R_{K_s} = 0.306$. Vrednosti $E(B-V)$ date su u IRSA katalogu (engl. Infrared Science Archive, skraćeno IRSA).⁴

Usled širenja Univerzuma, sjaj izvora koji stiže do posmatrača u određenom opsegu, centriranom na talasnu dužinu λ , zapravo potiče iz "užeg" opsega centriranog na $\lambda_0 = \lambda(1 + z)$. Za širokopojasnu fotometriju (engl. broadband photometry), K-korekcija daje transformaciju između posmatranog opsega i onog koji bi bio posmatran da je izvor na crvenom pomaku $z = 0$ i odnosi se na oba efekta: promenu širine opsega i pomeraj centralne talasne dužine (Humason et al., 1956; Oke & Sandage, 1968). Ova korekcija k_i , može se izraziti u magnitudama za proizvoljan filter i i izračunava se kao:

$$k_i = 2.5 \log(1 + z) + 2.5 \log \left[\frac{\int_0^\infty f_\lambda(\lambda) S_i(\lambda) d\lambda}{\int_0^\infty f_\lambda(\lambda/(1 + z)) S_i(\lambda) d\lambda} \right], \quad (6.1.7)$$

gde je f_λ fluks izvora, a $S_i(\lambda)$ funkcija širine opsega filtera i (Oke & Sandage, 1968). U praksi, međutim, pošto fluks izvora nije poznat, koriste se empirijske formule izvedene iz modela spektralne raspodele energije (engl. spectral energy distribution; skraćeno, SED) određenog broja objekata, koji dobro opisuju SED velikog broja galaksija. Znajući odgovor filtera, SED se može pomeriti za iznos crvenog pomaka izvora, kako bi se

²<https://galex.stsci.edu/casjobs/>.

³<http://skyserver.sdss.org/casjobs/default.aspx>.

⁴<http://irsa.ipac.caltech.edu/applications/DUST/>.

izračunala korekcija. K-korekcija izračunata je korišćenjem programa `Kcorrect` (Chilingarian et al., 2010).⁵ Ukratko, K-korekcija se vrši aproksimacijom polinoma niskog stepena u funkciji samo dva parametra: crvenog pomaka i boje. U proizvoljnom filteru i :

$$K_i(z, m_{f1} - m_{f2}) = \sum_{x=0}^{N_z} \sum_{y=0}^{N_c} a_{x,y} Z^x (m_{f1} - m_{f2})^y, \quad (6.1.8)$$

gde je $m_{f1} - m_{f2}$ boja u filterima $f1$ i $f2$, izabranih za dati filter i , z je crveni pomak, a N_z i N_c su stepeni polinoma.

U tezi su korišćene Petrosijanove magnitude u g i r filteru. Petrosijanove magnitude `petroMag`, preuzete su iz tabele `PhotoPrimaryDR7` baze podataka `CasJobs`.⁶ Obe magnitude su korigovane na gorepomenute efekte. Petrosijanove magnitude obuhvataju 98% fluksa galaksije sa eksponencijalnim profilom sjaja i oko 80% sjaja galaksija ranog tipa. Upravo iz ovog razloga, urađena je još jedna korekcija samo Petrosijanovih magnituda (Kronove magnitude obuhvataju $\approx 99\%$ fluksa), prema radu West et al. (2010), koja uračunava "izgubljeni fluks":

$$\log(\text{fluks}) = 9.87 - 9.28 * \log(r') + 2.56 * \log(R_{90}) + 1.34 * \log(b/a), \quad (6.1.9)$$

$$r = 22.5 - 2.5 * \log(10^{-0.4*(r'-22.5)} + 10^{\log(\text{fluks})}), \quad (6.1.10)$$

gde je r' magnituda u r filteru, R_{90} Petrosijanov radijus koji obuhvata 90% površinskog sjaja galaksije, b/a odnos male i velike poluose galaksije iz Sersikovog modela raspodele površinskog sjaja, a r korigovana magnituda, korišćena nadalje.

Za bliske infracrvene magnitude iz 2MASS kataloga, korišćene su tzv. ukupne magnitude, dobijene ekstrapolacijom radijalnog profila sjaja galaksije dalje od izofote na 20 $\text{mag}/''^2$, približno 4 puta duže od skale diska. Na ovaj način se dodaje još 10% - 20% fluksa galaksije (zavisno od morfologije). Iz GALEX-ovog kataloga izabrane su Kronove magnitude `nuv_mag` i `fuv_mag`, koje su merene programom `SExtractor`.

6.2 Masa različitih komponenata galaksije

HI podaci pružaju informaciju o crvenom pomaku, rotaciji galaksije i masi neutralnog vodonika, ali ne i o zvezdanoj masi. Infracrvena fotometrija omogućava dobijanje dodatnih informacija o morfologiji galaksija i luminoznosti. Odnos mase i sjaja u bliskom infracrvenom gotovo je nezavisan od istorije formiranja zvezda i bolje se može predvideti teorijskim modelima, te je infracrvena luminoznost najbolji izbor za izračunavanje zvezdane mase (Bell et al., 2003). Takođe, infracrvena K luminoznost je 5 do 10 puta manje osetljiva na prašinu i efekte zvezdane populacije od optičkih luminoznosti (Bell et al., 2003).

Korišćenjem korigovane, prividne m_k magnituda u bliskom infracrvenom Ks filteru, uz poznatu udaljenost objekta, može se izračunati apsolutna magnituda (6.1.2), a zatim i luminoznost (L):

$$M - M_{\odot} \equiv -2.5 \log \left(\frac{L}{L_{\odot}} \right), \quad (6.2.1)$$

gde su M , M_{\odot} apsolutne magnituda galaksije i Sunca, redom, a L i L_{\odot} luminoznosti galaksije i Sunca. Uz poznati odnos mase i sjaja za dati filter, može se dobiti zvezdana masa. Bell et al. (2003) daju relacije između boje i odnosa mase i sjaja za veliki opseg boja. U radu je korišćen odnos mase i sjaja u 2MASS-ovom Ks filteru:

$$\log \left(\frac{M_k}{L_k} \right) = -0.209 + 0.197(g - r). \quad (6.2.2)$$

Trivijalno, zvezdana masa se dobija:

$$\log M_k = \log \left(\frac{M_k}{L_k} \right) + \log L_k. \quad (6.2.3)$$

Dinamička masa galaksija, izračunata je prema relaciji datoj u radu Taylor et al. (2010):

$$GM_{\text{dyn}} = K_V(n)\sigma_0^2 R_e, \quad K_V(n) = \frac{73.32}{10.456 + (n - 0.95)^2} + 0.954 \quad (6.2.4)$$

gde je σ_0 centralna disperzija brzina, n Sersikov indeks, a R_e efektivni radijus. Korekcija $K_V(n)$ uključuje uticaj strukture galaksije na kinematiku zvezda. Centralna disperzija

brzina unutar aperture dijametara $3''$, mora se korigovati tako da se odnosi na površinu kruga unutar efektivnog radijusa. Korekcija se vrši prema Jorgensen et al. (1995) i Cappellari et al. (2006):

$$\sigma_0 = \sigma_{\text{ap}} \left(\frac{R_{\text{ap}}}{R_e/8} \right)^{0.066}, \quad (6.2.5)$$

gde je σ_{ap} disperzija merena unutar aperture, R_{ap} radijus aperture i iznosi $1.''5$, a R_e "kružni" efektivni radijus iz Sersikovog modela. Takozvani kružni radijus je zapravo radijus kružne aperture, za koju je korekcija validna i može se dobiti iz Sersikovog fita, preko odnosa male i velike poluose: $R_e = \sqrt{b/a} R_{\text{ser}}$, gde je R_{ser} efektivni radijus Sersikovog profila sjaja galaksije.

Masa tamnog haloa (M_{DM}) može se proceniti tako što se od dinamičke mase oduzme doprinos zvezdane i gasne komponente:

$$M_{\text{DM}} = M_{\text{dyn}} - M_{\text{k}} - M_{\text{HI}} - M_{\text{He}}, \quad (6.2.6)$$

gde je $M_{\text{He}} = 0.34M_{\text{HI}}$ masa elemenata težih od vodonika.

6.3 Metoda osnovnih komponenata

Višedimenzionalni prostor galaksija, uprkos raznolikosti galaksija ima konačan broj parametara koji značajno razlikuju jedne galaksije od drugih, ne samo u morfološkom smislu, nego i suštinski razlikuju mlade galaksije od starih, one koje su nastale u sudarima od onih koje su ostale izolovane, one kojima dominira tamna materija od onih gde je zvezdana komponenta značajnija itd. Sve ove osobine mogu se izraziti bilo posmatranim, bilo izvedenim veličinama, koje stoje u nekakvim međusobnim odnosima ili *relacijama skaliranja* (engl. scaling relations). Posebno su značajne relacije koje povezuju direktno merljive veličine sa udaljenošću do galaksija, koju je i danas teško precizno odrediti (npr. Tully-Fisher-ova relacija).

6.3.1 Prostor parametara

Višedimenzionalni prostor parametara nije nekakav *ad hoc* skup parametara, već se formira iz relacija koje opisuju osobine galaksija (relacije skaliranja) i fundamentalnih osobina galaksija (npr. starost galaksija). Koristeći poznate veze između nekoliko značajnih parametara, Garcia-Appadoo et al. (2009) daju uvid u višedimenzionalni prostor kreiran iz HI pregleda (HIPASS pregled). Njihov uzorak broji 195 galaksija, koje su zajedničke sa SDSS pregledom neba i imaju odgovarajuću optičku fotometriju. Oni analiziraju veliki broj parametara i potvrđuju pet značajnih korelacija:

$$L_r \sim L_g^{1.1},$$

$$\Sigma_g \sim L_g^{1/2},$$

$$M_{HI} \propto R_{50}^2,$$

$$M_{dyn} \propto L_g,$$

$$R_{90} \sim R_{50},$$

gde su R_{50} i R_{90} Petrosijanovi radijusi, $(g - r)$ optička boja, L_g luminoznost u g filteru, L_r luminoznost u r filteru, M_{HI} masa gasa, W_{20} širina HI linije, M_{dyn} ⁷ dinamička masa galaksije i Σ_g površinski profil sjaja u g filteru. Koristeći podatke iz ovog rada, Disney et al. (2008) izdvaja sledeće parametre kao značajne za PCA metodu: M_{dyn} , M_{HI} , L_g , R_{90} , R_{50} , $g - r$. Autori nalaze jednu statistički značajnu komponentu, koja se ne može identifikovati. Ovom prostoru u narednom poglavlju biće dodato još nekoliko parametara. U ovoj tezi, prvo je primenjena PCA metoda na α -uzorak galaksija u istom prostoru parametara, koji koriste Disney et al. (2008). U prostoru ovih parametara, PCA metoda daje *dve značajne komponente*: prvu koju u jednakoj proporciji čine svi parametri osim boje $g - r$ i drugu, kojom potpuno dominira boja. Prve dve komponente objašnjavaju

⁷ $M_{dyn} = (W_{20}/\sin i)^2 R_{50}/G$

83% varijanse sistema. Zatim je izvršeno testiranje, kako bi se našao optimalan skup parametara. Prvo je $g - r$ boja zamenjena drugim bojama dostupnim iz fotometrije (različitim kombinacijama magnituda). Uvođenjem boje $NUV - r$ u analizu, boja postaje izraženija u drugoj komponenti (veći kosinus pravca, tj. manji ugao). Uključivanje infracrvenih boja ne doprinosi objašnjenju ukupne varijanse sistema i nema efekta na komponente, osim što neznatno slabi amplitudu boje u drugoj komponenti. Dodavanjem starosti može se dobiti još jedna značajna komponenta kojoj u većoj meri doprinosi starost izražena preko H_β indeksa, nego modelovana starost (`ulyss` program). Starost dominira trećom komponentom. Dodavanjem metaličnosti prostoru parametara rezultati se ne menjaju. Dodavanjem centralne disperzije brzina, koja koreliše sa dinamičkom masom, boja još uvek najviše doprinosi drugoj komponenti, ali postaje značajna i disperzija brzina. Trećom komponentom i dalje dominira starost, a dodavanjem maksimalne rotacione brzine pojavljuje se i četvrta komponenta kojom ona dominira. Dodavanjem mase tamnog haloa (jednačina 6.2.6), rezultati analize ostaju nepromenjeni.

Disperzija brzina je značajna sama po sebi, pošto govori o haotičnom kretanju u centralnim delovima galaksije, nasuprot (uređenoj) rotaciji karakterističnoj za disk. Ona učestvuje u izrazima za dinamičku masu galaksija i njenu ukupnu energiju. Ima značajnu ulogu i u korelacijama (sigma-stepene relacije) i stoga se ne sme zanemariti. Sa druge strane, rotaciona brzina daje specifični ugaoni moment galaksije, zajedno sa masom zvezdane komponente i stoga je značajna za analizu. Ho (2007) pokazuje da disperzija brzina i rotaciona brzina ne korelišu značajno, tako da ostaje otvoreno pitanje postoji li veza između centralnog ovala galaksije i njenog haloa u smislu istorije nastanka i/ili evolucije. Takođe, nedovoljna jačina ove korelacije ukazuje na to da nema bliske veze između haotične i uređene energije sistema.

Konačan prostor parametara obuhvata: dinamičku masu M_{dyn} , masu zvezdane M_k i gasne M_{HI} komponente, boju $NUV - r$, kao indikatora specifične stope formiranja zvezda, Petrosijanove radijuse R_{50} i R_{90} , luminoznost u g filteru L_g , H_β Likov indeks kao indikator

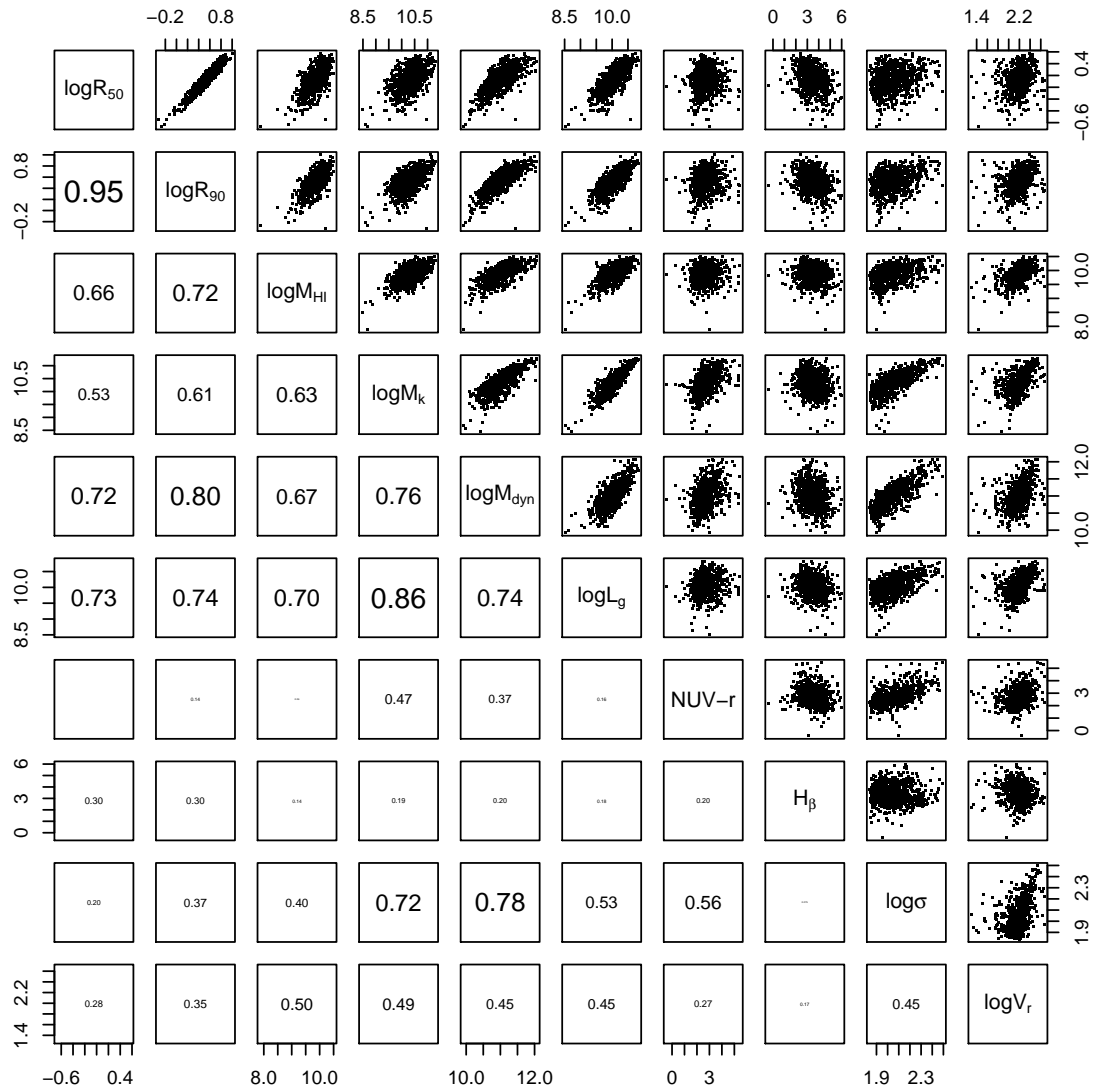

starosti, maksimalnu rotacionu brzinu V_r , kao indikatora specifičnog ugaonog momenta galaksija i disperziju brzina σ , kao indikatora dinamičke mase i ukupne energije galaksija. Iz α -uzorka izuzete su galaksije za koje je: Sersikov indeks $n > 10$, merena disperzija ispod instrumentalne rezolucije merenja ($V_d < 70$ km/s) ili iznad granice $V_d > 400$ km/s⁸, a rotaciona brzina $V_r > 600$ km/s. Ostaje 913 galaksija, čiji su ulazni parametri dovoljno precizno određeni za dalju analizu.

6.3.2 Diskusija

Svi parametri iz konačnog skupa, izračunati su u fizičkim jedinicama i logaritmovani (osim boje koja je po prirodi logaritamska veličina i indeksa H_β) za korelacionu analizu. U $\alpha.40$ katalogu dostupne su daljine do galaksija, pomoću kojih su odgovarajući parametri zavisni od daljine, prevedeni u fizičke jedinice. Razlog logaritmovanja leži u činjenici da se koeficijenti korelacije mogu računati samo na linearno zavisnim veličinama, kao i PCA metoda, s obzirom na to da kreira linearne kombinacije parametara. Korelacije su prikazane na slici 6.1. Ovde su na dijagonali naznačeni analizirani parametri; iznad dijagonale prikazane su vrednosti parametara sa osama, koje treba čitati sa dijagonale; ispod dijagonale dati su koeficijenti korelacije vizuelno uvećani prema jačini korelacije. Između Petrosijanovih radijusa javlja se degeneracija, ali će biti zadržani u krajnjoj analizi, jer oslikavaju fundamentalno svojstvo galaksija - površinski sjaj menja se eksponencijalno duž cele galaksije.

U konačnom prostoru parametara, koji oslikavaju fundamentalne osobine galaksija, primenjena je metoda osnovnih komponenata koristeći proceduru `princomp` programskog jezika R. U tabeli 6.1 prikazani su koeficijenti linearnih kombinacija ulaznih parametara, odnosno kosinusi pravaca koje polazni parametri zaklapaju sa sopstvenim vektorima (osnovnim komponentama, skraćeno OK). Što su apsolutne vrednosti kosinusa pravaca veće, to je značajniji doprinos datog parametra sopstvenom vektoru. Na primer, za

⁸Granična vrednost disperzije koju autori programa pPXF programa preporučuju je 400 km/s.

Slika 6.1: Korelaciona analiza: koeficijenti korelacije između ulaznih parametara (ispod dijagonale), vizuelno uvećani zavisno od jačine korelacije. Iznad dijagonale prikazani su grafici međusobne zavisnosti ulaznih parametara. Ose su naznačene u dijagonali.

kosinus pravca jednak 1.0, parametar bi u potpunosti odgovarao datom sopstvenom vektoru (bio bi identičan sa sopstvenim vektorom). Pored kosinusa pravaca, u zagradi je dato procentualno učešće (doprinos) svakog od razmatranih parametara pojedinačnim osnovnim komponentama. Sopstvena vrednost svake od osnovnih komponentata (OK), data je vrednošću λ . U poslednje dve vrste tabele 6.1, redom su date varijanse (VAR) i kumulativne varijanse (CUMVAR) pojedinačnih osnovnih komponentata u procentima. Rezultati statističke analize su sledeći: postoje najmanje tri statistički značajne, nezavisne komponente skupa analiziranih parametara, koje objašnjavaju 80% varijanse sistema (tabela 6.1). Ove komponente su linearne kombinacije ulaznih parametara, međusobno ortogonalne i čine novi koordinatni sistem u koji se mogu smestiti galaksije različitih morfologija, masa i struktura. Svaka od komponentata, kao linearna kombinacija ulaznih parametara, sadrži sve parametre sa određenom amplitudom, koja govori o tome u kojoj meri dati parametar doprinosi pomenutoj komponenti. Ukoliko je amplituda jednog od parametara značajno veća od svih drugih parametara, možemo identifikovati ovaj parametar sa datom komponentom. Osnovnih komponentata ima onoliko koliko ima ulaznih parametara, ali su statistički značajne samo one sa sopstvenom vrednošću $\lambda > 1$ (prema teoremi donje granice; Guttman (1954)). Konkretno, dobijeno je da postoje tri statistički značajne komponente. Prva i najznačajnija komponenta, ne može se identifikovati ni sa jednom od pojedinačnih osobina galaksija. Boja u ranijim radovima nije bila statistički značajna, a sada je to postala, uvećavajući dimenzionalnost. Od svih analiziranih parametara, ona daje najveći doprinos drugoj komponenti. Jedan značajan parametar koji je nedostajao u dosadašnjim radovima jeste starost galaksija. Ona uvećava dimenzionalnost i može se identifikovati sa trećom značajnom komponentom. Postoji indikacija o četvrtoj komponenti koja se može identifikovati sa maksimalnom rotacionom brzinom. Iako nije statistički značajna ($\lambda = 0.9$), moguće je da će to postati u nekom većem uzorku galaksija, koji bi raspolagao informacijom o pravoj maksimalnoj rotacionoj brzini, pošto jednosnopovski profili HI linija mogu imati samo jedan

maksimum i to ne mora biti pravi maksimum. Takođe, maksimalna rotaciona brzina izvedena iz širine HI linije uključuje korekciju za inklinaciju, što je još jedan nepouzdan parametar u analizi. Dakle, zaključak je da postoje *najmanje* tri, a moguće je i četiri dimenzije višedimenzionalnog prostora galaksija kakve vidimo danas.

Tabela 6.1: Za svaku osnovnu komponentu (OK), dati su kosinusi pravaca projekcija ulaznih parametara, a u zagradi procentualni doprinos svakog od analiziranih parametara osnovnim komponentama. Naglašene su dominantne vrednosti učesća. Poslednje tri vrste daju: vrednost sopstvenog vektora svake OK (λ), procenat objašnjene varijanse datom komponentom (VAR) i procenat objašnjene kumulativne varijanse (CUMVAR).

Sa slike 6.1, vidi se da sa prvom komponentom svi parametri osim boje i H_β indeksa korelišu jednako dobro i sa približno istim rasipanjem tačaka. Ova najznačajnija komponenta ne može se identifikovati, jer joj u jednakoj meri doprinose: Petrosijanovi radijusi R_{50} i R_{90} , dinamička masa M_{dyn} , zvezdana masa M_k , masa gasa M_{HI} i luminoznost L_g . Kod druge komponente, boja $NUV - r$ ima najveći nagib (zaklapa najveći ugao) i pokazuje najmanje rasipanje tačaka. Kod treće i četvrte komponente dominiraju H_β (starost) i rotaciona brzina V_r , redom. Projekcije ulaznih parametara na prve četiri osnovne komponente, prikazane su na slici 6.2.⁹ Dominacije pojedinih galaktičkih parametara vide se kroz najmanje rasejanje tačaka, kao najjasnije linearne zavisnosti. Prethodne analize višedimenzionalnog prostora galaksija nisu uključivale starost i disperziju brzina, te su se mogle svesti na jedan do dva fundamentalna parametra. Ovakav prostor parametara je nepotpun, pošto mu nedostaju parametri povezani sa fundamentalnim osobinama galaksija. Takođe, analizirane su samo spiralne galaksije, sa izuzetkom radova Disney et al. (2008) i Toribio et al. (2011).

6.3.3 Rezime metode osnovnih komponentata

Dakle, uključivanjem svih deset relevantnih parametara, koji ulaze u izraze za fundamentalne relacije i opisuju fundamentalne fizičke osobine galaksija (masa, energija i ugaoni moment), višedimenzionalni prostor galaksija svodi se na tri ključna parametra, sadržana u prva tri sopstvena vektora. Ova tri činioca odgovorna su za nastanak i evoluciju galaksija kakve vidimo danas.

Prva komponenta ne može se identifikovati ni sa jednim pojedinačnim parametrom, već joj u jednakoj meri doprinose: dinamička masa, masa zvezdane i gasne komponente, luminoznost i Petrosijanovi radijusi R_{50} i R_{90} . Uzimajući u obzir sve nabrojane parametre i oslanjajući se na postojeće radove iz ove oblasti, prvu komponentu možemo identifikovati

⁹Ovde su iz tehničkih razloga korišćene drugačije oznake: ($Hbeta = H_\beta$, $Mdyn = M_{\text{dyn}}$, $Mk = M_k$, $MHI = M_{\text{HI}}$ i $Vd = \sigma$).

Slika 6.2: Projekcije 10 analiziranih galaktičkih parametra na prve četiri osnovne komponente, redom. Ugao nagiba najboljeg linearnog fita je zapravo kosinus pravca dat u tabeli 6.1.

sa "veličinom" galaksija. Drugoj komponenti najveći doprinos daje boja i ona se može identifikovati sa "izgledom" galaksija. Treća komponenta je starost galaksija. Istaknuta je i četvrta komponenta, kojoj najviše doprinosi maksimalna rotaciona brzina i koja bi se stoga mogla identifikovati sa specifičnim ugaonim momentom galaksija. Ipak, ostaje pitanje njenog značaja u statističkoj analizi, s obzirom na to da joj je sopstvena vrednost manja od jedinice. Uključenjem morfološkog tipa galaksija, rezultati se ne menjaju.

Pionirski radovi primene PCA metode na galaksije sa merenim rotacionim krivama tretirali su samo spiralne galaksije iz heterogenih uzoraka i nalazili dve statistički značajne komponente (npr. Whitmore (1984)). Kasniji radovi (Toribio et al., 2011; Disney et al., 2008), iako zasnovani na HI pregledima nisu uključivali fundamentalne parametre poput disperzije brzina i starosti galaksija i nalaze jedan do dva značajna činioca. PCA metoda α -uzorka na manjem skupu parametara, poput onog predstavljenog u Disney et al. (2008), daje dve statistički značajne komponente. Druga komponenta se može identifikovati sa bojom, kao u Disney et al. (2008), ali za razliku od ovog rada ona je statistički značajna (ima sopstvenu vrednost $\lambda = 1.26$).

Nedostatak analize sprovedene u ovoj tezi leži u skromnoj spektroskopiji (nizak SNR), iz koje se dobijaju tri ključna parametra: disperzija brzina, indeks H_{β} i dinamička masa (izvedena iz disperzije brzina). Takođe, zavisno od daljine galaksije, spektar zahvata samo deo centralnog ovala i to različit. U julu 2016. godine najavljeno je prvo publikovanje trodimenzionalnih spektara galaksija prikupljenih pregledom celog neba (projekat MANGA¹⁰). Ovim bi se spektroskopske informacije učinile homogenim i umesto skalarnih vrednosti raspolagali bismo gradijentima što je zapravo potpuna informacija ekvivalentna onoj koja se dobija iz fotometrije. U trenutku kada je ova teza bila već završena, postao je javno dostupan ceo (100%) ALFALFA uzorak bliskih galaksija i 70% celokupnog pregleda (u tezi je korišćen prethodno dostupan tzv. $\alpha.40$ uzorak koji obuhvata 40% izvora). Bilo bi interesantno u budućem radu ponoviti analizu na novom, većem uzorku galaksija.

Poglavlje 7

Rezime i zaključci

Jedan od glavnih ciljeva ove teze jeste nalaženje najmanjeg broja parametara koji opisuju višedimenzionalni parametarski prostor galaksija i njihova identifikacija. Ulazni parametri analize odabrani su iz većeg skupa parametara nakon detaljne analize, tačnije modelovanja i testiranja, tako da oslikavaju fundamentalne osobine galaksija, kao što su dinamička masa, energija, ugaoni moment itd. Prethodni radovi obuhvatali su manji prostor opservabli, te su rezultovali manjim brojem značajnih parametara. Takođe, nisu uzimali u obzir ultraljubičasti deo spektra, odakle je boja $NUV - r$ korišćena u ovom radu, koja se pokazala boljom u analizi od optičkih i infracrvenih boja. Vredno je pomenuti da je analiza sprovedena na većem uzorku galaksija od prethodnih radova. Takođe, analizirane galaksije prate lokalnu morfološku raspodelu galaksija. Drugim rečima, zastupljeni su svi tipovi galaksija u proporciji u kojoj postoje u lokalnom Univerzumu.

7.1 Rezime

U prvom, uvodnom poglavlju dat je pregled relevantnih tema, obrađenih u narednim poglavljima i dat je opis sadržaja teze. U drugom poglavlju, predstavljen je uzorak galaksija korišćen u ovoj tezi. Diskutovana je njegova reprezentativnost u morfološkom smislu.

Korišćenjem nekoliko kriterijuma, potvrđeno je da je α -uzorak morfološki reprezentativan u lokalnom Univerzumu.

U trećem poglavlju izmerena je kinematika zvezda uključujući više momente raspodele brzina zvezda duž pravca posmatranja. Ona je računata pomoću empirijskih (posmatranih) i sintetičkih (modelovanih) spektara zvezda. Poređenjem sa dostupnim rezultatima, ustanovljeno je *sistematsko* potcenjivanje merene disperzije u slučaju korišćenja sintetičkih spektara. Korišćenjem sintetičkih spektara zasnovanih na istoj empirijskoj bazi, ustanovljeno je *sistematsko* precenjivanje disperzije. U svakom slučaju, postojanje sistematskog odstupanja (u bilo kom pravcu) pokazuje da je bolje koristiti empirijske spektre zvezda. Ipak, oni moraju biti brižljivo odabrani da bi bili reprezentativni ili veoma brojni, kako bi obezbedili dobru pokrivenost osobina svih tipova zvezda. Pokazano je da aproksimacija funkcije raspodele brzina duž pravca posmatranja Gausijanom utiče na veličine koje se ne mogu direktno meriti, već se izvode iz merene disperzije brzina, kao što je virijalna masa, masa centralne crne rupe itd. Naime, ovim se zanemaruju viši momenti raspodele i unosi greška u izračunavanje disperzije koja, u srednjem, smanjuje virijalnu masu za 13% u empirijskom slučaju, dok se u sintetičkom slučaju ovaj efekat može zanemariti. Izvršen je i niz statističkih testova na višem momentu raspodele brzina (h_4), koji potvrđuju indikaciju da eliptične i sočivaste galaksije dele poreklo, pošto, prema testovima, potiču iz iste raspodele.

U četvrtom poglavlju izmereni su spektralni indeksi galaksija, imajući u vidu njihovu vezu sa starošću i metaličnošću. Nezavisno od indeksa, urađeno je modelovanje celih spektara (indeksi se, suprotno, izračunavaju na uskim delovima spektra), korišćenjem iste empirijske biblioteke zvezdanih spektara, ali modelovane tako da obuhvati veći opseg starosti i metaličnosti. Indeks H_β najbolje koreliše sa modelovanom starošću, dok indeks gvožđa $\langle Fe \rangle' = 1/3 (Fe_{5015} + Fe_{5270} + Fe_{5335})$ najbolje koreliše sa metaličnošću i pritom, što je važno zbog postojanja degeneracije između starosti i metaličnosti, veoma slabo koreliše sa indeksom H_β . Kao usputni rezultat, modelovanje celih spektara daje i disperziju

brzina. Poređenjem disperzija zasnovanih na empirijskim spektrima i modelovanim spektrima, otkriveno je sistematsko precenjivanje vrednosti disperzije. Iz ovog razloga, ali i činjenice da u krajnjoj analizi osnovnih komponenata Likovi indeksi korelišu bolje sa drugim parametrima, u daljem radu je umesto modelovane starosti korišćen indeks H_{β} , kao njen najbolji indikator.

U petom poglavlju, predstavljena je dvodimenzionalna analiza površinskog profila sjaja galaksija, sa ciljem da se dobiju strukturni parametri za dalju analizu. Naime, sve galaksije su modelovane sa tri jednokomponentna (Devokulerov, Sersikov i eksponencijalni profil) i tri dvokomponentna modela kod kojih je druga komponenta eksponencijalni disk, a prva: Devokulerov, Sersikov i eksponencijalni centralni oval. Na ovaj način izračunati su sledeći parametri: efektivni radijus Sersikovog modela, skala diska eksponencijalnog profila i Sersikov indeks. Na primer, Sersikov indeks zajedno sa disperzijom brzina ulazi u izraz za dinamičku masu, jedan od fundamentalnih parametara korišćen u metodi osnovnih komponenata.

Konačno, u šestom poglavlju predstavljena je statistička metoda osnovnih komponenata, sa ciljem da se višedimenzionalni prostor parametara svede na što manji broj međusobno nezavisnih parametara, koji opisuju prirodu galaksija. Prethodni slični radovi analizirali su manji parametarski prostor i, kao posledicu dobijali manji broj rezultujućih parametara (dimenzija). Međutim, nedostatak fundamentalnih parametara čini ove prostore nepotpunim. Rezultati metode osnovnih komponenata sugerišu da je familija galaksija najmanje troparametarska.

7.2 Zaključci

U ovoj tezi urađena je statistička analiza galaktičkih parametara, dobijenih iz modelovanja kinematike zvezda, računa Likovih indeksa i modeliranja površinskog sjaja galaksija iz α -uzorka, koji broji 2180 galaksija i sačinjen je iz ALFALFA $\alpha.40$, SDSS

DR7, 2MASS i GALEX baze podataka. Za sve galaksije raspolažemo optičkom i radio-spektroskopijom i fotometrijom od ultraljubičastog do bliskog infracrvenog dela spektra. α -uzork je reprezentativan u morfološkom smislu, jer sadrži galaksije različitih morfoloških tipova u onom odnosu u kome su one zastupljene u lokalnom Univerzumu. Ovo je najveći uzorak galaksija na kome je izmerena detaljna kinematika zvezda uključujući više momente raspodele brzina duž pravca posmatranja. Uzorak ove veličine omogućava primenu raznih statističkih metoda iz kojih se mogu izvući brojni zaključci:

- i) Empirijska biblioteka zvezdanih spektara Elodie je superiorna u odnosu na druge empirijske, ali i sintetičke biblioteke.
- ii) Negausovska korekcija disperzije brzina značajna je za spektre $\text{SNR} > 50$.
- iii) Promena h_4 Gaus-Hermitovog koeficijenta sa morfološkim tipom galaksija sugerise da su orbite zvezda dominantno radijalne za sve morfološke tipove galaksija i ovaj trend se uvećava idući od galaksija kasnog tipa do galaksija ranog tipa.
- iv) Nezavisno od morfološkog tipa galaksije, raspodela h_4 Gaus-Hermitovog koeficijenta je zašiljena. Repovi raspodele ovog koeficijenta pokazuju da se koeficijent asimetrije povećava idući od galaksija kasnog tipa do galaksija ranog tipa.
- v) Postoji indikacija da eliptične i sočivaste galaksije imaju isto poreklo.
- vi) Otkrivena je nova kombinacija Likovih indeksa gvožđa, koja bolje koreliše sa metaličnošću od indeksa gvožđa korišćenog u literaturi ($\langle \text{Fe} \rangle$). Novi indeks je dobar indikator metaličnosti i veoma slabo koreliše sa starošću galaksija.
- vii) Postoje najmanje tri, a moguće je i četiri dimenzije višedimenzionalnog prostora fundamentalnih galaktičkih osobina, odgovornih za ustrojstvo galaksija, kakvo vidimo danas. Prve dve dimenzije ne mogu se identifikovati ni sa jednim od galaktičkih parametara, ali ih možemo shvatiti kao "veličinu" i "izgled" galaksija. Trećom dimenzijom dominira starost galaksija, a četvrtom maksimalna rotaciona brzina.

7.3 Perspektive za budući rad

Nalaženje i identifikacija fundamentalnih parametara, koji određuju evoluciju galaksija može se poboljšati korišćenjem većeg uzorka galaksija, koji bi se mogli *homogenizovati* uzimajući u obzir integralni spektar koji pokriva uvek isti region. Ovo se može postići korišćenjem trodimenzionalne spektroskopije koja će već u julu 2016. godine biti dostupna (MANGA projekat). Naime, spektroskopske veličine biće moguće izmeriti unutar istog radijusa, što će umanjiti aproksimativna rešenja svođenja na isti radijus. Sve ovo doprineće smanjenju rasipanja tačaka, koje slabi korelacije merenih veličina. Sličan efekat javlja se i kod fotometrijskih parametara, jer su rezolucije slika različite (veličine piksela). Već postoje metode koje omogućavaju da se sve slike svedu na istu rezoluciju (naravno, najlošiju) i da se unutar iste aperture mere magnitude i sa istim brojem detalja rade dekompozicije. Međutim, ovaj zadatak i vremenski i hardverski prevazilazi ovu tezu.

U trenutku kada je ova teza bila već završena, postao je javno dostupan veći ALFALFA uzorak bliskih galaksija (70% celokupnog pregleda) od α -uzorka korišćenog u tezi (koji obuhvata 40% izvora). Bilo bi interesantno u budućem radu ponoviti analizu na većem uzorku galaksija, kako bi se utvrdilo da li je moguće eliminisati pomenute nedostatke.

Iako su galaksije iz HI pregleda prostorno nekorelisane, bilo bi zanimljivo videti kako neki parametar indikativan za okruženje galaksija utiče na konačnu analizu. I naravno, iako je to daleka budućnost, informacije o rotacionoj krivoj galaksija, mogle bi značajno promeniti rezultate. Ali, ovakav pregled neba je jako zahtevan i sigurno neće još dugo biti realizovan, ako bude ikada. I, za kraj, nedovoljno poznavanje prirode tamne materije verovatno je veliki nedostatak postojeće analize. Dakle, predstavljeni rad se može poboljšati na nekoliko frontova. Očekujem da se iz sinergije trodimenzionalne spektroskopije i prostorne raspodele HI (rotacionih krivih) u budućnosti može otkriti prava dimenzionalnost prostora galaksija.

Dodatni materijal

Dodatak A

Postupak kreiranja uzorka

Konačan α -uzorak od 2180 galaksija dobijen je počev od $\alpha.40$ kataloga galaksija, koje imaju merene spektre u SDSS DR7 bazi (Haynes et al., 2011). Ovaj katalog je predat Kataloškom serveru SDSS-a (engl. SDSS Catalog Archive Server, skraćeno CAS)¹. Prvo, uzorak je "filtriran" kroz SDSS DR7 tabele da bi se obezbedila dobra fotometrija i pouzdani mereni crveni pomaci galaksija:

```
SELECT a.AGCNr2 as name, sp.ra, sp.dec, sp.specobjID as sdss_specobjid,  
sp.objID as sdss_objid, sp.z, sp.zErr  
INTO mydb.a40_SDSSDR7_noflags  
FROM mydb.a40_alfalfa as a  
JOIN SpecPhotoAll sp ON a.SpectObjId3 = sp.specObjID  
WHERE sp.zWarning = 0 AND sp.mode=1 AND sp.type=3 AND  
((sp.flags & 0x10000000) != 0) AND ((sp.flags & 0x8100000c00a0) = 0) AND  
(((sp.flags & 0x400000000000) = 0) or (sp.psfmagerr_r <= 0.2)) AND  
(((sp.flags & 0x100000000000) = 0) or (sp.flags & 0x1000) = 0)
```

¹<http://skyserver.sdss.org/casjobs/>

²Identifikacioni broj Alfalfa galaksija iz Haynes et al. (2011).

³Jedinstvena spektroskopska identifikacija iz SDSS DR7 za Alfalfa galaksije iz Haynes et al. (2011).

Identifikacija je vršena koristeći jedinstvenu spektroskopsku identifikaciju iz Haynes et al. (2011) baze, sa nekoliko dodatnih ograničenja sugerisanih od strane SDSS DR7, sa ciljem izdvajanja kvalitetnih podataka. Ovako je inicijalni uzorak od 9966 galaksija smanjen na 6732 galaksije. Drugi "filter" smanjio je uzorak na 4568 galaksije, kada su traženi odgovarajući pandani galaksija u GALEX GR6, ponovo koristeći CAS, gde već postoji tabela GALEX GR6 i SDSS DR7 prostornih identifikacija (xSDSSDR7). Radijus pretrage je 3" (dijametar SDSS spektrografa):

```
SELECT a.name, a.ra, a.dec, x.objid, a.sdss_objid, a.sdss_specobjid
INTO mydb.a40_SDSSDR7_GalexGR6
FROM photoObjAll AS p
JOIN xSDSSDR7 AS x ON p.objid = x.objid
JOIN mydb.a40_SDSSDR7_noflags AS m ON m.objID = x.SDSSobjID
JOIN photoextract AS e ON e.photoExtractID = p.photoExtractID
WHERE distanceRank = 1 AND reverseDistanceRank = 1
AND distance <= 3.0 AND e.nuvintfi != 'null' AND e.fuvintfi != 'null'
AND nuv_flux != -999 AND fuv_flux != -999
```

Poslednji korak je pretraga 2MASS baze za objektima (poziciona pretraga) pomoću Infracrvne naučne arhive (engl. IPAC Infrared Science Archive, skraćeno IRSA).⁴ Za polazni katalog sa koordinatama (RAJ2000, DECJ2000), unutar radijusa od 3" traženi su svi objekti iz XSC kataloga (engl. 2MASS All-Sky Extended Source Catalog), uz uslov da imaju dobru fotometriju:

```
cc_flg != 'a' AND cc_flg != 'z' AND j_flg_k20fe = 0 AND h_flg_k20fe = 0
AND k_flg_k20fe = 0
```

⁴<http://irsa.ipac.caltech.edu/applications/2MASS/PubGalPS/>.

Dodatak B

Osnovni podaci o galaksijama iz α -uzorka

U Dodatku A opisan je način kreiranja konačnog α -uzorka iz $\alpha.40$ kataloga, u kome je svaka galaksija numerisana Alfalfa brojem i raspolaže (normalizovanom) verovatnoćom pripadanja određenom morfološkom tipu (E, S0, Sab i Scd). Ceo $\alpha.40$ katalog zatim je ukršten sa nekoliko drugih kataloga, kako bi se dobila fotometrija od ultraljubičastog do bliskog infracrvenog dela spektra. Osnovne informacije pomoću kojih se svaka galaksija iz konačnog α -uzorka može naći i identifikovati u korišćenim katalozima (SDSS, GALEX GR6 i 2MASS XSC), dati su u tabeli B.1.

Tabela B.1: Osnovni podaci o galaksijama iz α -uzorka: (1) Naziv galaksije iz α .40 kataloga; (2,3) rektascenzija (RA) i deklinacija (DEC) u stepenima; (4,5) fotometrijski i spektroskopski identifikacioni broj u SDSS DR7 CasJobs tableli specPhotoAll; (6) 2MASX identifikacioni broj iz XSC kataloga; (7) crveni pomak; (8) srednji odnos signala prema šumu za spektroskopiju i (9,10,11,12) normirane verovatnoće pripadanja galaksije jednom od morfoloških tipova: E, S0, Sab i Scd, preuzete iz α .40 kataloga.

Dodatak E

Definicija regiona spektralnih indeksa

U ovoj tezi mereno je svih 25 Likovih spektralnih indeksa definisanih u radovima Worthey et al. (1994); Worthey & Ottaviani (1997). Indeksi su definisani kao površina ispod "pseudokontinuum" apsorpcione linije (nalik ekvivalentnoj širini), merena unutar centralnog regiona, čijim granicama odgovaraju druga i treća kolona tabele E.1 (λ_{c1} & λ_{c2}). Pseudokontinuum je linija koja spaja tačke srednje vrednosti plavog (λ_{b1} & λ_{b2}) i crvenog (λ_{r1} & λ_{r2}) regiona sa obe strane centralnog regiona. Ovo nije pravi kontinuum, pošto je definisan lokalno za svaki spektralni indeks i otuda naziv pseudokontinuum. Talasne dužine u tabeli E.1 preuzete su sa web sajta koji održava Gaj Vorti (Guy Worthey)¹ date u vazduhu i prenete u vakuum pomoću IDL-ove procedure `airtovac`, pošto su talasne dužine SDSS spektara vakuumske.

¹<http://astro.wsu.edu/worthey/html/system.html>

Tabela E.1: Talasne dužine (u vakuumu) regiona koji definišu Likove indekse. Kolone: 1) naziv indeksa, 2,3) leva i desna granica centralnog regiona indeksa, 4,5) leva i desna granica "plavog" pseudokontinuumu, 6,7) leva i desna granica "crvenog pseudokontinuumu", 8) oznaka atomskog (0) ili molekulskog (1) indeksa.

Dodatak F

Likovi indeksi – merenja i poređenje

U tezi je mereno svih 25 Likovih indeksa, definisanih u radovima Worthey et al. (1994); Worthey & Ottaviani (1997). Mereni indeksi su korigovani na Likovu rezoluciju i širenje nastalo kao posledica nenulte disperzije brzina galaksija i dati su u tabelama F.1 i F.2, za empirijsku biblioteku i F.3 i F.4, za sintetičku biblioteku. Rezultati su upoređeni sa postojećim merenjima iz SDSS, MPA-JHU i OSSY baze podataka. Takođe, poređenje je izvršeno i sa sintetičkom zvezdanom bibliotekom. Na slikama F.1, F.2, F.3, F.4, F.5 i F.6, date su merene vrednosti indeksa za empirijski slučaj (na x -osi), dok su simbolima različitih boja predstavljeni rezultati iz drugih kataloga. Vidi se da je poređenje sa SDSS rezultatima najspornije (sive zone), a posledica je sistematike nastale usled toga što su mereni spektri zadržali SDSS rezoluciju, te su sistematski veći. Kod indeksa podložnih kontaminaciji emisionih linija, vidi se sistematika ka nižim vrednostima indeksa, pošto prisustvo emisionih linija smanjuje površinu unutar koje se indeks meri (npr. Fe_{5015}). Sintetičke biblioteke na kojima je zasnovano merenje kinematike daju sistematski manje vrednosti indeksa, kao posledicu sistematskog potcenjivanja disperzije brzina.

Tabela F.1: Korigovani Likovi indeksi galaksija iz α -uzorka za empirijsku biblioteku Elodie. U prvoj koloni dat je Alfalfa naziv galaksije, zapravo identifikacioni broj. Zatim su redom date starost (Myr) i $[\text{Fe}/\text{H}]$ i nadalje prvih 15 Likovih indeksa, od Ca_{4227} do G_{4300} . Preostalih 10 Likovih indeksa dati su u narednoj tabeli.

Tabela F.3: Korigovani Likovi indeksi galaksija iz α -uzorka za sintetičku biblioteku. U prvoj koloni dat je Alfalfa naziv galaksije, zapravo identifikacioni broj. Zatim je redom dato prvih 14 Likovih indeksa, od Ca₄₂₂₇ do G₄₃₀₀. Preostalih 11 Likovih indeksa dati su u narednoj tabeli.

Alfalfa naziv	Ca ₄₂₂₇	Ca ₄₄₅₅	CN ₁	CN ₂	Fe ₄₃₈₃	Fe ₄₅₃₁	Fe ₄₆₆₈	Fe ₅₀₁₅	Fe ₅₂₇₀	Fe ₅₃₃₅	Fe ₅₄₀₆	Fe ₅₇₀₉	Fe ₅₇₈₂	G ₄₃₀₀

Tabela F.4: Korigovani Likovi indeksi galaksija iz α -uzorka za sintetičku biblioteku. U prvoj koloni dat je Alfalfa naziv galaksije, zapravo identifikacioni broj. Zatim je redom dato preostalih 11 Likovih indeksa (prvih 14 dato je u prethodnoj tabeli F.3), od H_{β} do TiO_2 .

Alfalfa naziv	H_{β}	$H_{\delta,A}$	$H_{\delta,F}$	$H_{\gamma,A}$	$H_{\gamma,F}$	Mg ₁	Mg ₂	Mg _b	NaD	TiO ₁	TiO ₂

Slika F.1: Poređenje merenja 24 Likova indeksa dobijenih korišćenjem empirijskih zvezdanih spektara sa dostupnim merenjima (indeks H_β nedostaje, pošto je prikazan u tekstu teze). Poređenje se vrši sa: SDSS (sive tačke), MPA-JHU (crvene tačke), SIN (sintetički slučaj prikazan plavim tačkama) i OSSY merenjima (zelene tačke). Na obe ose je dat Likov indeks u nazivu grafika, samo je na x -osi dat "empirijski" indeks.

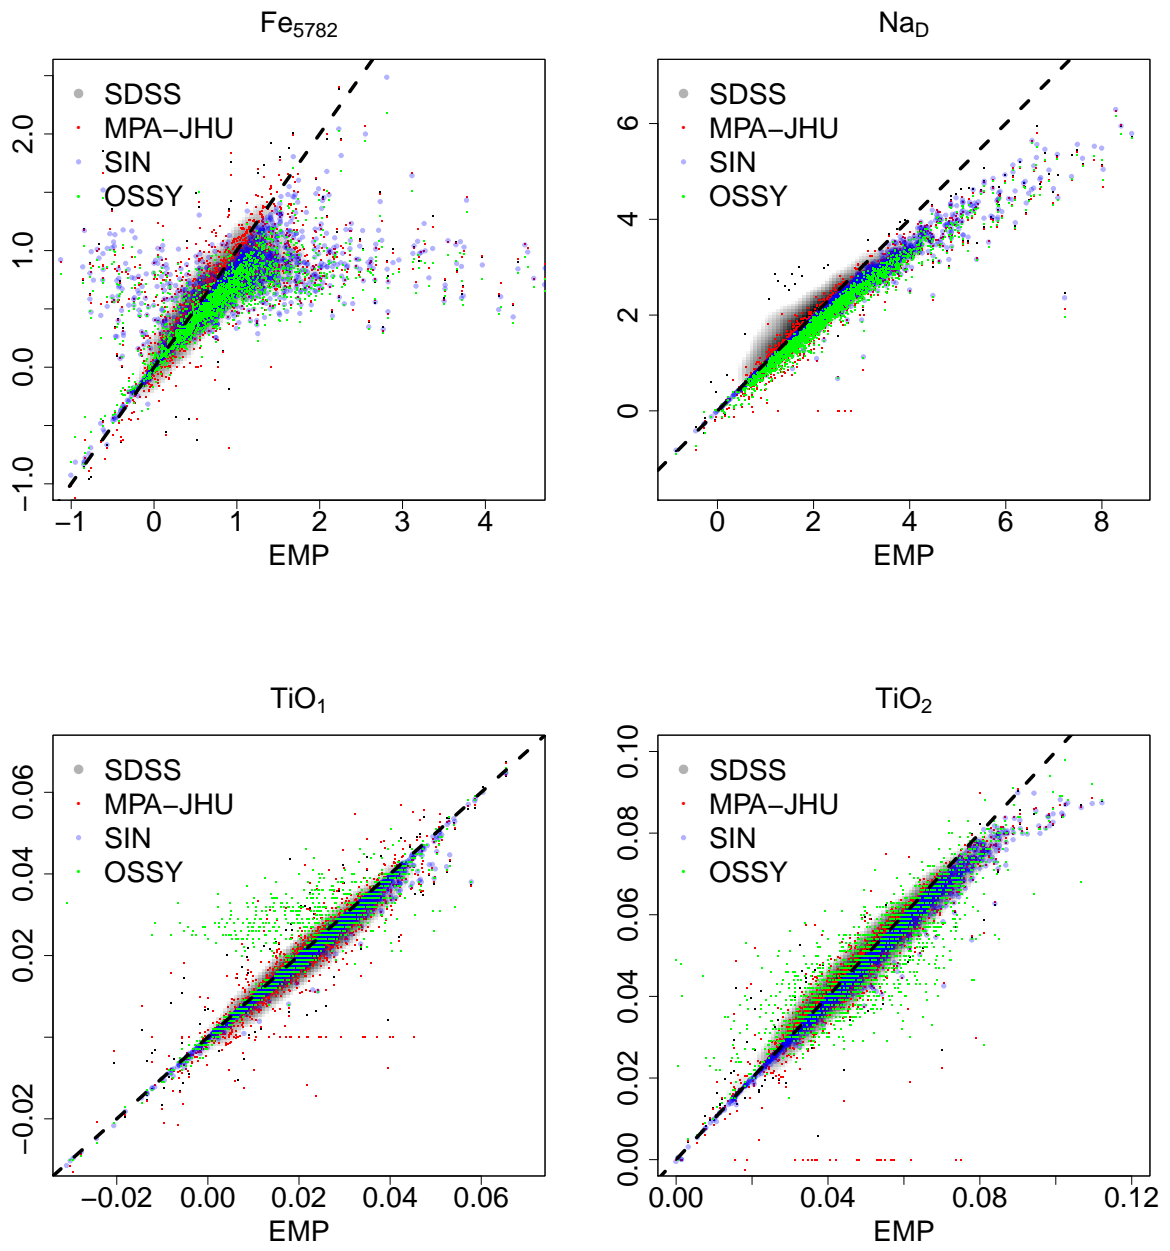

Slika F.2: Opis dat na slici F.1.

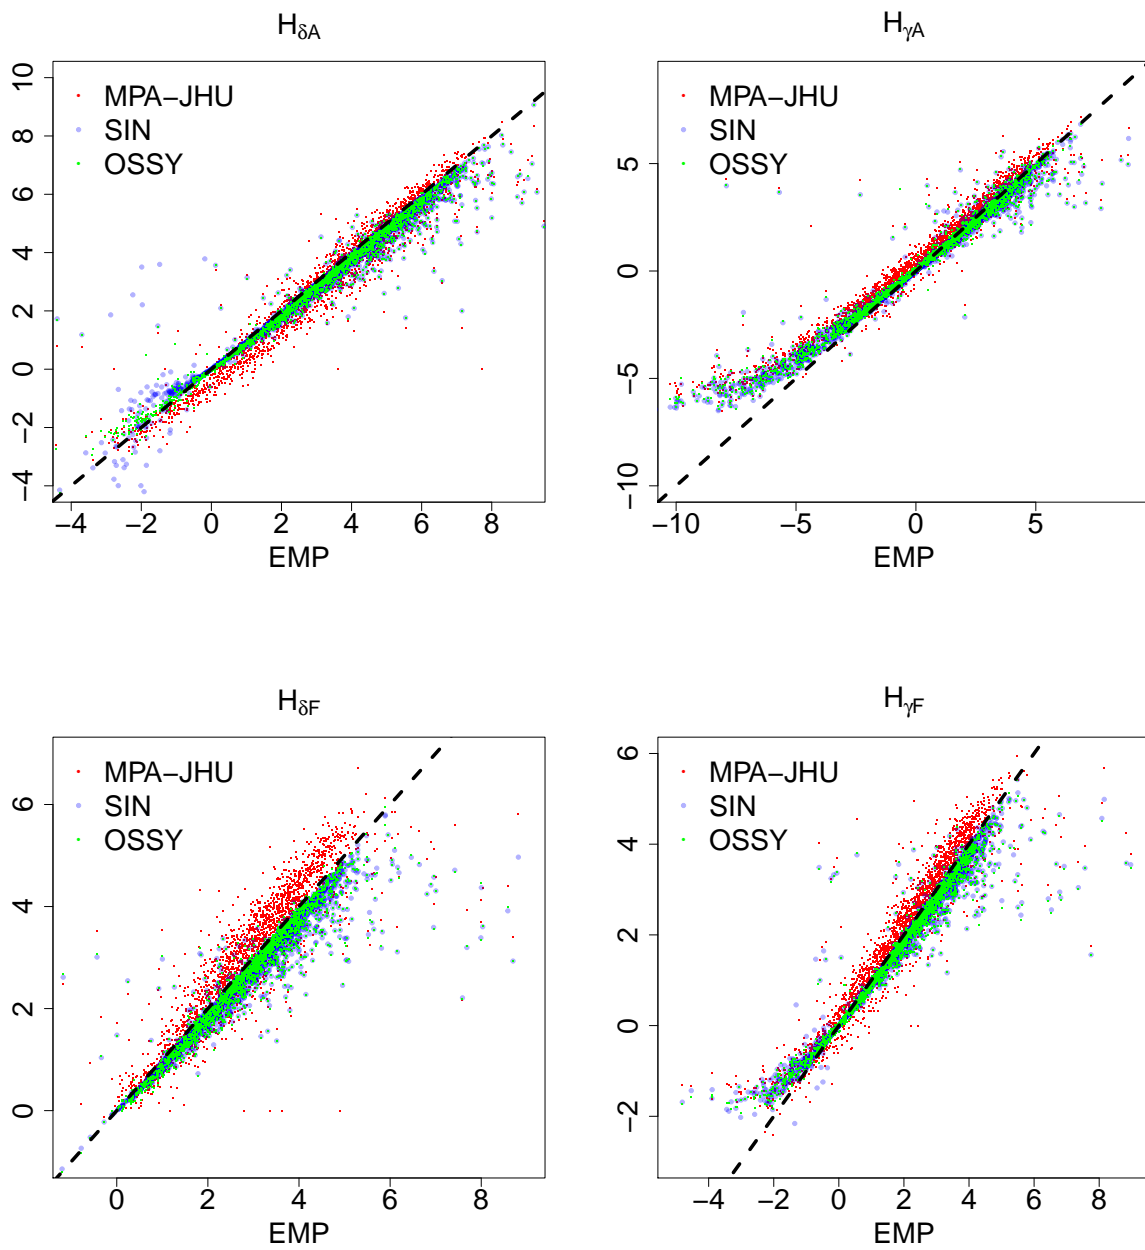

Slika F.3: Opis dat na slici F.1.

Slika F.4: Opis dat na slici F.1.

Slika F.5: Opis dat na slici F.1.

Slika F.6: Opis dat na slici F.1.

Primer feedme fajla

Feedme fajl je fajl koji podešava početne parametre fita za višekomponentno razlaganje radijalnih profila sjaja galaksije za program Galfit. U ovom fajlu prvo se zadaju potrebni globalni parametri, odnosno slike: slika galaksije (A), naziv izlaznog fajla koji sadrži ulaznu sliku galaksije, dobijeni model i rezidualne fita u ekstenzijama fits fajla (B), zatim slede σ slika (C), PSF zvezde¹ (D), celobrojni faktor pomoću kojeg se od ulazne PSF funkcije može dobiti PSF slika sa više piksela (engl. oversampled) u slučaju da ima nedovoljno piksela (npr. loša rezolucija) (E), slika maske koja maskira sve nenulte piksele i tako ih isključuje iz fita (F), fajl sa graničnim uslovima kojim se mogu nametnuti granice finalnih parametara fita (G), region slike unutar kojeg program fituje objekat sa pozadinom (H), veličina regiona konvolucije, ujedno i veličina fitovanog regiona (I), nulta magnituda (J), veličina piksela u lučnim sekundama (K) itd. Zatim slede početni parametri dve komponente. Naziv funkcije kojom se fituje (0),² koordinate centra galaksije (1), efektivna magnituda (3), efektivni radijus (4), eksponencijalni indeks ($n = 1$ je eksponencijalna funkcija koja opisuje disk, a $n = 4$ Devokulerov profil koji dobro opisuje

¹Reziduali se izračunavaju tako što se model konvoluiru sa tačkastom funkcijom izvora (PSF) i onda oduzme od fluksa galaksije.

²Galfit podržava sledeće funkcije: Sersikov, eksponencijalni, Devokulerov, Nukerov, Fererov i Mofatov profil, Gausijan i još nekoliko funkcija.

klasične ovale) koji može biti bilo koji ceo broj (5), odnos male i velike poluose galaksije (9), pozicioni ugao galaksije (10) i parametar koji može isključiti datu komponentu iz krajnje slike. Celi brojevi 1/0 pored svakog parametra govore programu Galfit da li da varira vrednost parametra (1) ili da ga drži fiksiranog tokom fita (0).

Dodatak H

Rezultati dekompozicije

U tezi je modelovan površinski sjaj galaksija iz α -uzorka pomoću programa Galfit, koristeći jednokomponentne i dvokomponentne modele. Rezultati dekompozicije, odnosno modelovani parametri dati su u tabelama: H.1, H.2, H.3, H.4 i H.5.

Jednokomponentni modeli podrazumevaju modelovanje površinskog sjaja cele galaksije jednim modelom i to: Devokulerovim, eksponencijalnim i Sersikovim zakonom (tabele H.1 i H.2). Takođe, urađeno je modelovanje dvokomponentnim modelima, od kojih je jedna komponenta centralni oval opisan Devokulerovim, eksponencijalnim i Sersikovim zakonom, a druga disk, opisan eksponencijalnim zakonom (tabele H.3, H.4 i H.5).

Tabela H.1: Jednokomponentni modeli galaksija iz α -uzorka: Devokulerov i eksponencijalni profil površinskog sjaja, redom. U prvoj koloni dat je Alfalfa naziv galaksije, kao identifikacioni broj iz α .40 kataloga. Zatim su za oba jednokomponentna modela dati redom: efektivni sjaj (μ_e^{MODEL}) u $\text{mag}''/2$, efektivni radijus (R_e^{MODEL}) u pikselima, koji se množenjem sa veličinom piksela od 0."396 može dobiti u lučnim sekundama, odnos male i velike poluose (b/a^{MODEL}), pozicioni ugao (PA^{MODEL}) u stepenima i χ^2_{MODEL} , gdje je $\text{MODEL} = \text{DEV}$ ili EXP .

Alfalfa naziv	μ_e^{DEV} ($\text{mag}''/2$)	R_e^{DEV} (pix)	b/a^{DEV}	PA^{DEV} ($^\circ$)	χ^2_{DEV}	μ_e^{EXP} ($\text{mag}''/2$)	R_e^{EXP} (pix)	b/a^{EXP}	PA^{EXP} ($^\circ$)	χ^2_{EXP}

Tabela H.2: Jednokomponentni Sersikov model galaksija iz α -uzorka. U prvoj koloni dat je Alfalfa naziv galaksije, kao identifikacioni broj iz α .40 kataloga. Zatim su za Sersikov jednokomponentni model dati redom: efektivni sjaj (μ_e^{SER}) u mag/'², efektivni radijus (R_e^{SER}) u pikselima, koji se množenjem sa veličinom piksela od 0.''396 može dobiti u lučnim sekundama, odnos male i velike poluose (b/a^{SER}), pozicioni ugao (PA^{SER}) u stepenima i χ_{SER}^2 .

Tabela H.3: Dvokomponentni model galaksija iz α -uzorka: Devokulerovalni oval i ekspanencijski disk. U prvoj koloni dat je Alfalfa naziv galaksije, njen identifikacioni broj iz α .40 kataloga. Zatim su dati redom: efektivni sjaj (μ_e^{DEV}) u $\text{mag}/''^2$, efektivni radijus (R_e^{DEV}) u pikselima, koji se množenjem sa veličinom piksela od $0.''396$ može pretvoriti u lučne sekunde, odnos male i velike poluose (b/a^{DEV}), pozicioni ugao (PA^{DEV}) u pikselima, odnos male i velike poluose (b/a^{EXP}), pozicioni efektivni sjaj (μ_e^{EXP}) u $\text{mag}/''^2$, efektivni radijus (R_e^{EXP}) u pikselima, odnos male i velike poluose (b/a^{EXP}), pozicioni ugao (PA^{EXP}) u stepenima za ekspanencijski model i ukupan χ^2 fita.

Tabela H.4: Dvokomponentni model galaksija iz α -uzorka: eksponencijalni oval i eksponencijalni disk. U prvoj koloni dat je Alfalfa naziv galaksije, njen identifikacioni broj iz α 40 kataloga. Zatim su dati redom: efektivni sjaj (μ_e^{EXP}) u $\text{mag}/''^2$, efektivni radijus (R_e^{EXP}) u pikselima, koji se množenjem sa veličinom piksela od 0.''396 može pretvoriti u lučne sekunde, odnos male i velike poluose (b/a^{EXP}) i pozicioni ugao (PA^{EXP}) u stepenima za eksponencijalni oval i efektivni sjaj (μ_e^{EXP}) u $\text{mag}/''^2$, efektivni radijus (R_e^{EXP}) u pikselima, odnos male i velike poluose (b/a^{EXP}) i pozicioni ugao (PA^{EXP}) u stepenima za eksponencijalni disk i ukupan χ^2 fita.

Alfalfa naziv	μ_e^{EXP} ($\text{mag}/''^2$)	R_e^{EXP} (pix)	b/a^{EXP}	PA^{EXP} ($^\circ$)	μ_e^{EXP} ($\text{mag}/''^2$)	R_e^{EXP} (pix)	b/a^{EXP}	PA^{EXP} ($^\circ$)	χ^2

Tabela H.5: Dvokomponentni model galaksija iz α -uzorka: Sersikov centralni oval i ekspanzija disk. U prvom koloni dat je Alfalfa naziv galaksije, njen identifikacioni broj iz α .40 kataloga. Zatim su dati redom: efektivni sjaj (μ_e^{SER}) u $\text{mag}/''^2$, efektivni radijus (R_e^{SER}) u pikselima, koji se množenjem sa veličinom piksela od 0.''396 može pretvoriti u lučne sekunde, odnos male i velike poluose (b/a^{SER}), pozicioni ugao (PA^{SER}) u stepenima i Sersikov indeks n^{SER} za Sersikov centralni oval i efektivni sjaj (μ_e^{EXP}) u $\text{mag}/''^2$, efektivni radijus (R_e^{EXP}) u pikselima, odnos male i velike poluose (b/a^{EXP}) i pozicioni ugao (PA^{EXP}) u stepenima za ekspanziju disk i ukupan χ^2 fita.

Alfalfa naziv	μ_e^{SER} ($\text{mag}/''^2$)	R_e^{SER} (pix)	b/a^{SER}	PA^{SER} ($^\circ$)	n^{SER}	μ_e^{EXP} ($\text{mag}/''^2$)	R_e^{EXP} (pix)	b/a^{EXP}	PA^{EXP} ($^\circ$)	χ^2

Biografija autora

Mr Ana Lalović je rođena 04. 06. 1979. godine u Beogradu. Osnovnu školu i gimnaziju je završila u Beogradu. Studije astrofizike na Matematičkom fakultetu Univerziteta u Beogradu upisala je 1998. i diplomirala 2004. godine, sa prosečnom ocenom 9.12. Ubrzo nakon diplomiranja mr Ana Lalović se zapošljava na Astronomskoj opservatoriji u Beogradu (2005. godine), gde radi i danas. Poslediplomske studije završila je u decembru 2008. godine, odbranom magistarske teze pod naslovom "Lajman-alfa šuma na niskom i srednjem crvenom pomaku i model minihaloa", pod mentorstvom dr. Milana Ćirkovića. Od početka svoje naučne karijere, objavila je 7 (izvor ADS) naučnih radova u domaćim i međunarodnim časopisima, a učestvovala je i na mnogim međunarodnim i domaćim naučnim skupovima.

Изјава о ауторству

Име и презиме аутора Ана (Слободан) Лаловић

Број индекса _____ / (по старом) _____

Изјављујем

да је докторска дисертација под насловом

Спектроскопска и фотометријска анализа блиских галаксија различитих

морфолошких типова

- резултат сопственог истраживачког рада;
- да дисертација у целини ни у деловима није била предложена за стицање друге дипломе према студијским програмима других високошколских установа;
- да су резултати коректно наведени и
- да нисам кршио/ла ауторска права и користио/ла интелектуалну својину других лица.

Потпис аутора

Изјава о коришћењу

Овлашћујем Универзитетску библиотеку „Светозар Марковић“ да у Дигитални репозиторијум Универзитета у Београду унесе моју докторску дисертацију под насловом:

Спектроскопска и фотометријска анализа блиских галаксија различитих морфолошких

типова

која је моје ауторско дело.

Дисертацију са свим прилозима предао/ла сам у електронском формату погодном за трајно архивирање.

Моју докторску дисертацију похрањену у Дигиталном репозиторијуму Универзитета у Београду и доступну у отвореном приступу могу да користе сви који поштују одредбе садржане у одабраном типу лиценце Креативне заједнице (Creative Commons) за коју сам се одлучио/ла.

1. Ауторство (CC BY)
2. Ауторство – некомерцијално (CC BY-NC)
3. Ауторство – некомерцијално – без прерада (CC BY-NC-ND)
4. Ауторство – некомерцијално – делити под истим условима (CC BY-NC-SA)
5. Ауторство – без прерада (CC BY-ND)
6. Ауторство – делити под истим условима (CC BY-SA)

(Молимо да заокружите само једну од шест понуђених лиценци.
Кратак опис лиценци је саставни део ове изјаве).

Потпис аутора

У Београду, 10. јун 2016. године

1. **Ауторство.** Дозвољаваате умножавање, дистрибуцију и јавно саопштавање дела, и прераде, ако се наведе име аутора на начин одређен од стране аутора или даваоца лиценце, чак и у комерцијалне сврхе. Ово је најслободнија од свих лиценци.

2. **Ауторство – некомерцијално.** Дозвољаваате умножавање, дистрибуцију и јавно саопштавање дела, и прераде, ако се наведе име аутора на начин одређен од стране аутора или даваоца лиценце. Ова лиценца не дозвољава комерцијалну употребу дела.

3. **Ауторство – некомерцијално – без прерада.** Дозвољаваате умножавање, дистрибуцију и јавно саопштавање дела, без промена, преобликовања или употребе дела у свом делу, ако се наведе име аутора на начин одређен од стране аутора или даваоца лиценце. Ова лиценца не дозвољава комерцијалну употребу дела. У односу на све остале лиценце, овом лиценцом се ограничава највећи обим права коришћења дела.

4. **Ауторство – некомерцијално – делити под истим условима.** Дозвољаваате умножавање, дистрибуцију и јавно саопштавање дела, и прераде, ако се наведе име аутора на начин одређен од стране аутора или даваоца лиценце и ако се прерада дистрибуира под истом или сличном лиценцом. Ова лиценца не дозвољава комерцијалну употребу дела и прерада.

5. **Ауторство – без прерада.** Дозвољаваате умножавање, дистрибуцију и јавно саопштавање дела, без промена, преобликовања или употребе дела у свом делу, ако се наведе име аутора на начин одређен од стране аутора или даваоца лиценце. Ова лиценца дозвољава комерцијалну употребу дела.

6. **Ауторство – делити под истим условима.** Дозвољаваате умножавање, дистрибуцију и јавно саопштавање дела, и прераде, ако се наведе име аутора на начин одређен од стране аутора или даваоца лиценце и ако се прерада дистрибуира под истом или сличном лиценцом. Ова лиценца дозвољава комерцијалну употребу дела и прерада. Слична је софтверским лиценцама, односно лиценцама отвореног кода.
